N

THE NEW PSY TRY.

Delivered before the Royal College of ns of Edinburgh on March 8th, 10th, and 15,

BY W. H. B. STODDA D. LOND.,
F.R.C.P. LON
LECTURER IN MENTAL DISEASE, ST. T HOSPITAL, ETC.

ABSTRACT OF LECT I.[1]

(*Delivered on March*

MR. PRESIDENT AND GENTLE -Another important psychological mechan which often serves as an indicator of repres omplexes, not only in nervous disorder, but als everyday life, is "projection." The peculiarity o phenomenon is that the effects of the repre complex are attributed by the individual pos ing it not to himself, but to some other person. few examples will explain my meaning. Peop ho are guilty of some failing, imperfection, weakness, of which they are ashamed, are exce ngly liable to attribute the same fault to others. a thief loses an article his first thought is tha somebody has stolen it from him, and the man w is ever ready to disbelieve any statement made t him is himself a person who is habitually economi l of the truth. The dishonest financier is always o the alert lest somebody should swindle him, and h is exceedingly intolerant of anybody who succeeds in doing so. The man who is unfaithful to his wife is usually suspicious that she may have been unfaithful to him, and how often have we all heard an asylum patient declare that his wife is insane, or a drunkard accuse his consort of insobriety. Self-reproach is so unpleasant to consciousness that it is repressed and sublimated into reproach of other people.

THE NEURONS.

I now propose to discuss various matters that have been elucidated by psycho-analytic methods respecting the neuroses, psychoneuroses, and psychoses. Freud recognises two neuroses proper—viz., neurasthenia and the anxiety neurosis. Probably a few cases of hypochondriasis are due to the same etiological factors as thes euroses and should therefore be included in the sa e group.

Neurasthenia.

Neurasthenia is a term which hith to has been used very loosely, and the separation o the anxiety neurosis as a distinct disease is due to the clinical insight of Freud. The term "neurasthe ia" is now limited to a class of case which ex ibits very definite symptoms, the chief of which an undue tendency to fatigue. This is well demo strated in ergographic tracings from neurasthen patients. In a normal person such tracing show a gradual increase of power at the beginning of the e periment so that the lever rises more and more ith each successive contraction. This is ascribed to he effect of practice. Subsequent contractions emain at the same level before fatigue sets in, when the level rises less and less until, the finger becoming absolutely useless, the tracing becomes a straight line. With a neurasthenic, on the other hand, the initial increase of power due to the effect of practice is not shown. The first few contractions may be of an average height, but fatigue sets in immediately and the contractions become weaker and weaker. The same phenomenon is shown in experiments devised for the purpose of investigating the laws of mental fatigue. In Weygandt's method, for instance, the patient is given a sheet of paper with columns of figures to be added. He starts at the first column and at the end of a minute writes down his result so far as he has gone. Then he passes to the next column, adds for a minute and puts down the result as before, and so on through the whole series. In a normal person at first the effect of practice is noticeable, in that the added portions of the column get longer and longer until, fatigue setting in, they grew shorter and shorter. In the neurasthenic, on the other hand, the added portions shorten from the very first. Mistakes in the addition also occur earlier than in a normal individual. The so-called "irritable eye" exemplifies the muscular fatigue, the patient complaining that the eyes ache on reading for a short time, although no error of refraction can be found. Examination with the perimeter soon fatigues the retina and, unless carried out quickly, the visual field will be found contracted or spiral.

These patients are anxious enough to be busy about their affairs like other people; but all effort, mental or physical, leads to an intense feeling of fatigue. In many cases, even the thought of doing anything causes the patient to tremble and to break into a profuse perspiration. Other symptoms are a sense of pressure on the top of the head, often localised to one spot on the left of the middle line, and various paræsthesias, especially of the joints and muscles and the back of the head over the occipital spine. The last is explained as a "crawling" or "screwy" sensation and was aptly described by one patient, whose case was related to me, as a feeling as if there were a blackbeetle inside the skull lying on its back and kicking to get on its legs again. Feelings of abdominal discomfort also occur and there may be hypochondriacal notions respecting the genito-urinary apparatus. Similar symptoms frequently occur in states of general debility, such as chlorosis, and in the early stages of organic nervous disease such as disseminated sclerosis or general paralysis. In these conditions the case should, of course, not be labelled "neurasthenia"; but when the above symptom-complex occurs independently of any other disease, then we have to deal with a case of true neurasthenia. In all cases of this kind, without exception, there is always to be found one essential etiological factor—viz., sexual excess. In the majority of cases this takes the form of masturbation, but in a few patients the disease is traceable to frequent nocturnal pollutions, and I have come across a still smaller number of neurasthenics who, being habitual roués, owe their neurosis to excessive indulgence in normal sexual intercourse. Such cases differ in recovering easily and rapidly as soon as the cause of their malady is explained and removed. Suitable advice and recommendations as to mental hygiene are the proper remedy; but it is often necessary to carry out a certain amount of psycho-analysis in order to trace and uproot the complexes which constitute the foundation of such irregular sexual impulses.

The Anxiety Neurosis.

The "anxiety neurosis" is characterised, as its name implies, by a persistent state of anxiety or fear, usually without obvious cause, but sometimes initiated by some real cause for anxiety. This state is always out of proportion to its cause, and

---

Lectures I. and II. were published in THE LANCET of March 20th (p. 583) and 27th (p. 639) respectively.

318260

NHW

the other symptoms of the neurosis are exaggerations of the normal physical signs of fear. Such are irregularity and an increased frequency of the pulse, palpitation, anginal attacks, general vasomotor constriction with coldness and blueness of the extremities, dryness of the mouth, perspiration (especially of the hands), polyuria, diarrhœa, respiratory oppression and air hunger, even attacks of asthma, vertigo, tremor, attacks of ravenous appetite, nausea and sometimes actual vomiting, night terrors and insomnia, hyperæsthesia for visual impressions and especially for noises, and a general apprehensiveness. Such patients are liable to exacerbations of their various symptoms in which the feeling of terror may be extremely severe with a feeling of congestion in the head and a dread of impending death. It is even said that there may be temporary loss of consciousness, but I have not seen such a case.

Freud and all who have subsequently investigated the matter are agreed that the anxiety neurosis owes its origin to an accumulation of mental excitement which finds no somatic outlet, and, further, that this excitement is almost always, probably always, of a sexual nature. Accordingly we meet with this neurosis among engaged couples who cannot afford to get married, in widows and widowers, in women whose husbands practise coitus interruptus (this is the commonest cause), in women during the climacteric whose husbands have reached senility, and in patients who with great effort have renounced masturbation. There are other important contributory factors. Heredity is one, and the condition also arises from overwork and exhaustion, especially after severe illness and prolonged watching by the bedside of a sick relative by night as well as by day. Unfortunately the obvious remedy for such a neurosis is usually impracticable, and it is my custom in these cases to seek by means of a short analysis interests of the patient into which his repressed energy may be directed (sublimation of the sexual impulse) and, in the meantime, to prescribe some anaphrodisiac medicine, my favourite mixture for such purposes being a combination of camphor with the extract of black willow.

The Psychoneuroses and Psychoses.

The psychoneuroses and psychoses are on an entirely different plane from the neuroses. The neuroses, as we have seen, owe their origin to existing causes, probably of a chemical nature, at the time of the malady, but the psychoneuroses and psychoses are compromise formations between repressed wishes and the forces which repress them; that is to say that their mechanism is exactly the same as that of dreams. The obvious differences between dreams and the psychoneuroses are that in the one the subject is asleep and desires to go on sleeping, while in the other he is awake; and also that dreams are normal while psychoneuroses are abnormal.

[Dr. Stoddart here illustrated by the imaginary case of a younger step-sister unfairly subordinated to the rest of the family, how the different endings possible to the well-known story of Cinderella might produce ideas of persecution or dementia præcox or hysterical paraplegia.]

Hysteria.

Freud's theory of hysteria depends on the recognition of the infantile development of sexuality. Events occur during childhood which at the time have no sexual significance, but the recollection of them after ma [illegible] disproportionately exciting because puber [illegible] the meantime incomparably increased the [illegible] g capacity of the sexual apparatus. T [illegible] nscious infantile memories influence the [illegible] exual life of the individual and may be [illegible] rming cause of masturbation. Such hy [illegible] ates are subconscious rather than unconsci [illegible] ifestations of hysteria. Sometimes, howeve [illegible] antasies or memories assume an unconsciou [illegible] and then we have the so-called hysteric [illegible] ks. These consist of a series of emotional d [illegible] which are rendered comprehensible when [illegible] hysician has discovered the underlying tho [illegible] or he is then able to see that such emotiona [illegible] ifestations are such as might be expected t [illegible] ur in response to the given stimulus.

Lastly, we h [illegible] "conversion hysteria" which results from [illegible] rsistent strife between some painful memor [illegible] d the restraint of the censor from its comin [illegible] the surface, the result of the struggle being [illegible] mpromise whereby the idea by distortion beco [illegible] converted into a somatic symptom, some bod [illegible] motor or sensory innervation or inhibition.

Psycho-analys [illegible] is to be regarded as the most radical form of [illegible] reatment of hysteria and other functional men [illegible] disorders to be presently discussed, but I mi [illegible] t here refer to other methods in common use. W [illegible] ir-Mitchell's "rest-cure" is quite fashionable at [illegible] e present time and undoubtedly gives good resu ts in many cases, provided it be used rationally and in combination with some psychical influe ce at the same time. Suggestion is most common y used, and Weir-Mitchell's private opinion of the whole procedure was that it acted mainly as a suggestive agency. The prolonged mental and physical rest are beneficial, the removal from home surroundings has the advantage of withdrawing the patient from an environment which has usually proved somewhat irritating, the massage and possibly the electricity tend to improve metabolism, and the over-feeding is well suited to patients who are ill-nourished. Let me say at once, however, that this method is worse than useless in any other condition than hysteria, and even in this disease failures are far from uncommon. Moreover, the expense is often as great as in psycho-analysis.

Hypnotism ay be employed with advantageous and often dra tically successful results in hysteria. Hypnosis is uch more easily achieved in this disease than [illegible] other mental disorders, and it may be used in on [illegible] of three ways: (1) to get the patient into an ext mely suggestible mood so that suggestion of r overy may be given; (2) to recover buried mem ries; or (3) to get the patient to react emotionally o buried memories.

The Compulsion Neurosis.

The com ulsion neurosis is a disease which shows itse in a large number of ways. The patients ha e a clear intellect and good memory, and they a e well orientated in time and place, but they suffe from mental symptoms into which morbidity hey have a clear insight. They suffer from irre ressible thoughts which often take the form of metaphysical questionings such as "When was the beginning of all things?" "What existed before that?" "Who created God?" or they attach undue importance to superstitions; or they cannot help repeating in their minds things they have heard. Many suffer from morbid fears or morbid irresistible impulses. Some of these patients have feelings of *incompleteness* in action, in intellectual problems, in emotional reaction, and in perception. Others have strange feelings of unreality and of depersonalisation, called by Janet psycholeptic crises. Formerly this condition was called "obsessional insanity," a term which was justifiable in that it offered no explanation. The mind is obsessed or besieged by such thoughts, fears, or impulses. Janet advanced a step by recognising what he called a "splitting of consciousness" or "mental dissociation" induced by a "lowering of the psychological tension," the psychical response of a psychasthenic to his environment being inadequate. Freud regards the compulsion neurosis as a disease of the unconscious, and as having a purely sexual basis, regarding the symptoms as substitutions for certain repressed sexual ideas and emotions.

[Dr. Stoddart here discussed Freud's views and those of Dr. Ernest Jones, concluding that psycho-analysis has proved to be the only really successful method of treating the compulsion neurosis, but hypnotism may be used in much the same way as for hysteria—viz.: (1) for suggestion, (2) to recover buried memories, and (3) to obtain an emotional reaction to a repressed complex. He briefly discussed other modes of treatment, and continued:]

Maniacal Depressive Insanity.

Maniacal depressive insanity is a disorder in which the patient is liable to attacks of mania, melancholia, or stupor, these being in some cases accompanied with or replaced by some delusional state. It is useless to attack this psychosis while the patient is passing through one of these acute phases of the disorder. Radical treatment of the disease must be undertaken during a period of sanity or, as the populace would say, during a "lucid interval." It is interesting, moreover, that psycho-analysts, who have had experience of these cases, have come to the conclusion that a very short analysis is most successful in effecting a cure, while a complete analysis, in the Freudian sense, only leads to relapse, but, as I said before, many psycho-analysts of experience differ from me on this point.

Dementia Præcox.

Dementia præcox has been most carefully studied by Jung from a psychological point of view, and the conclusion at which he arrives is that there is a remarkable psychological resemblance between it and hysteria. The complexes and the mechanism of their repression are exactly the same, yet hysteria is an eminently curable disease while dementia præcox is conspicuously incurable. The catatonic symptoms can easily be conceived as purely repressive devices, and it has been definitely proved in some cases that certain stereotyped actions are distorted representations of the fulfilment of repressed wishes; but at the same time we must not lose sight of the fact that these same symptoms also occur in certain organic cerebral diseases whose origin is at least much more organic than psychical. Again, the question is not yet absolutely settled whether dementia præcox is a psychogenic or organic disease. Alzheimer and others have described areas of gliosis in the deepest layers of the cortex, others have discovered fatty degeneration of the nerve cells, others, again, have observed cerebellar changes, all of which might very well be due to excess or defect of certain internal secretions. This idea, surmised by Kraepelin, has been rendered probable by Mott's discovery that certain glands possessing internal secretions, especially the ovaries and testes, are more or less atrophied in dementia præcox. On the other hand, Jung appears to have cured, or at least considerably ameliorated, some cases of dementia paranoides by psycho-analysis only. Jung recognises all these difficulties and gets out of them by supposing that the mental conflicts of dementia præcox give rise to toxins which act deleteriously upon the cerebral substance. I must confess that to me this idea does not appeal very strongly, but Kraepelin, who will have nothing to do with psycho-analysis, is, curiously enough, rather pleased with the suggestion.

The chief characteristic of patients suffering from dementia præcox is that they are living a dream and in the end completely retire from the world of reality (autism). Up to the present very little psychological investigation of the disease has been made, but we hope to learn much from the investigation now going on at Zürich. For the present, therefore, we must regard the pathology of dementia præcox as still undetermined.

Paranoia.

The last disease I must submit for your consideration is paranoia. This is a mental disorder of the fourth or fifth decade as a rule, and it is characterised by the progressive development of systematised delusions. The patients being of a suspicious temperament see hidden meanings in incidents which possess no unusual value for the ordinary man, and from the inevitable accumulation of such misinterpretations they evolve a system of delusions which vary from patient to patient. The cases are divided into two main classes: (1) the eccentrics or mattoids, the borderland cases of insanity, including faddists and cranks of all kinds; and (2) the egocentrics, including patients who suffer from delusions of persecution, jealousy, exaltation, and ill-health (hypochondriacs). All these patients are perfectly clear mentally, have no hallucinations, behave well and can think intelligently apart from their particular delusions, but they are firmly convinced that there is nothing mentally wrong with them, and therefore always feel aggrieved when they are involuntarily placed under care for their malady.

Since the advent of our new psychiatry many patients of the above-mentioned class have been analysed by modern psychological methods all over the civilised world, and the outcome has been the remarkable discovery that paranoia is a psychosis erected on the invariable basis of repressed homosexuality. Naturally enough the idea that a person has homosexual inclinations is usually repugnant to him; he refuses to admit it to himself, and it is repressed into the unconscious. Should such repression fail, the homosexual complex reappears in consciousness in the disguised form of paranoia or, I may add, as dementia paranoides, for it has been shown that the same psychical mechanism is at work in this variety of dementia præcox, designated by Kraepelin in his most recent edition, by the way, as "paraphrenia."

Although psycho-analysis has been successful in elucidating the psychology of this disease the method usually fails as a mode of treatment. I understand, however, that some psycho-analysts have effected a cure and many have alleviated the patient sufficiently to enable him to go about his business with a certain degree of mental comfort without molesting those people with whom he is brought into contact. Recovery is said to have been effected in a few cases of fairly recent origin by a method which somewhat resembles psycho-analysis, but differs from it in that the physician seeks, in the first instance, to obtain a positive transference before tackling the disease itself. He gets the patient to give a complete history of his life, endeavouring meanwhile to discover incidents and characteristics which have a bearing on his delusional state, and to disclose them. During the whole of this process, which takes 20 to 30 hours, he accepts the patient's point of view throughout until he ultimately gains his whole confidence and convinces him of his friendship, without, however, actually encouraging his delusions or agreeing with every word he says. Then, when a suitable opportunity offers, he suggests that the patient may have come to an erroneous conclusion about some quite insignificant occurrence. After a few more sittings, as opportunity offers, he points out another minor occasion when the patient might have been mistaken. So he goes on until he sees his chance for tackling the main delusion and pointing out that even here he may have also been mistaken. The physician takes advantage of any attitude of doubt and completes the cure by "therapeutic conversation." The whole procedure requires an enormous amount of tact, patience, and skill. Moreover, the physician must be familiar with these mechanisms of paranoia which have been discovered by the psycho-analytic method.

CONCLUDING REMARKS.

The main object of these lectures has been to expound the principles of psycho-analysis proper, its technique, the psychological mechanisms which it has disclosed, and the bearing of these mechanisms, not only on many of the patients in the asylums of Great Britain, but also on an enormous number of people pursuing their ordinary vocations in spite of curable mental worries or spending an enormous proportion of their time and income in nursing homes. The physician who will undertake the radical cure of these poor sufferers will earn the gratitude of society as well as that of the patients, which is always unbounded; but he must be a man of courage, for he will have to face the opposition of the "herd" for many years to come. In spite of all we may say, the subject of sex will remain taboo, yet no physician of experience can deny the enormous rôle played by sexual conflicts in the genesis of the neuroses. I do think that cases sometimes occur in which the psychogenetic conflict is non-sexual, but they are so rare that I can see the psycho-analytic literature of the future augmented by reports of such cases as curiosities.

Although I attach so much importance to psycho-analysis, I hope that no words of mine will detract from the systematic investigation of cases by other methods. It would be deplorable, for instance, if attention to psychological investigation should detract from the work of the clinical laboratory and thus allow a positive Wassermann reaction, so common in dementia præcox, for example, to be overlooked.

It has often been said that the frequency of mental disease is due to the effect of civilisation, to the hurry, bustle, and struggle for existence associated with urban life, to defective sanitation, insufficient sleep, overwork, poverty, brain-fag, education, and a host of other things incident on civilisation. With all our modern conveniences, the Poor-law, hygienic surroundings, hospitals, comfortable railways with restaurant cars and sleeping accommodation, typewriters and telephones, such a view is manifestly erroneous.

That insanity is the result of civilisation is obvious to anybody who looks the facts in the face; but psycho-analysis has revealed that the essential factor is not hurry, bustle, and brain-fag, but the repression of the instincts enforced by civilisation.

It is not to be supposed that the prophylaxis of insanity lies in letting loose the reins of licentiousness and depravity. The problem is far more intricate than this, and it is not likely that it will be solved in the present century, much less in our own time. The mystery at present surrounding sex and birth problems must be removed by systematic education of the young in such matters, early marriage must be made more possible than existing circumstances will permit, and old men and parents will have to remember the days of their own youth when they enact the laws which are to govern society. Moreover, the whole populace will have to be educated in such matters before any serious change can be accomplished.

CEREBRO-SPINAL MENINGITIS.

WITH NOTES ON TWO EPIDEMICS.

BY E. NORMAN BUTLER, B.A. CANTAB., M.R.C.S. ENG., L.R.C.P. LOND.,

MEDICAL OFFICER, MAGADI RAILWAY, BRITISH EAST AFRICA; LATE HOUSE PHYSICIAN, CASUALTY OFFICER, AND RESIDENT ANÆSTHETIST, ST. THOMAS'S HOSPITAL: LATE CAPTAIN, EAST AFRICAN MEDICAL SERVICE.

Cerebro-spinal meningitis, or spotted fever, is a disease of great importance to the practitioner, for though nowadays large epidemics are rare in England, the occurrence of the disease in small numbers is frequent in our larger towns. In East Africa the disease has assumed characters so virulent that it is the dread of the native and the bugbear of the employer of native labour. This is not surprising, for in 1913 it killed, in one tribe, numbers variously estimated at 20,000 to 40,000.

It is a curious feature of the disease that there are places in East and Central Africa where it is always endemic and seldom epidemic, as, for instance, Uganda in general and the coast town of Mombasa, whilst in the highlands of British East Africa the endemic form is not often seen, and when the disease occurs it is usually in the form of an epidemic of greater or less virulence.

In the second of the epidemics to be here described the persons involved were natives of Uganda and the borderland between British East Africa and Uganda, who were brought down to the coast to act as military porters in connexion with the campaign against German East Africa. Whilst in Mombasa three or four cases of a clearly sporadic nature occurred, following the usual custom of that town, where amongst the natives post-basic meningitis is of continual occurrence.

First Series.

The first epidemic that came to my notice was of a much milder character than the second; it occurred at almost the same place in the highlands as the second, but amongst natives whose normal habitat more normally approximates to the altitude in which they were then living. In all, I had 8 cases in this epidemic, resulting in 4 deaths and 4 complete recoveries. Besides these a small number of cases occurred amongst natives who were not under my care, and these were treated by Dr. Nicholls.

I must make apology for lack of scientific methods. I have been, all through, unable to obtain a lumbar-puncture needle in this country, and lack of a bacteriological laboratory rendered microscopical examination of pus my only means of investigation of the organism.

As regards the second series of cases—the more important one—scientific observation was rendered even less possible, by reason of the difficulties naturally encountered in such work when it is done in connexion with the transport arrangements of an expeditionary force on active service.

CASE 1A.—Aged about 25. Physique poor. History of sudden onset of pain at the back of the neck and across the shoulders, and severe occipital and vertical headache. On the second day head retraction was marked, but not excessive, Kernig's sign positive; abdominal and epigastric reflexes absent; knee-jerks normal. The plantar reflex, as with all natives, was not obtainable, owing to the thickness of the soles of the feet. On the third day there was purulent conjunctivitis in the right eye, the pus showing a Gram-negative diplococcus with an intracellular distribution. The case showed no further features of interest, and made an uneventful recovery.

CASE 2A.—Aged 20 years. Physique fair. In general the case was almost precisely similar to the last, save that the conjunctivitis affected both eyes, the pus from which showed the diplococcus, and there was a nasal discharge of thick, yellow, creamy pus, which also contained intracellular diplococci. After four days the patient became unconscious, with very marked head retraction, and died on the eighth day. At the necropsy I found thick yellow pus in the pia-arachnoid involving the brain from base to vertex, descending into the greater fissures and all along the spinal cord.

The following is a different type of case showing more severe onset, but proceeding to complete recovery.

CASE 3A.—Aged 15. Physique poor. Onset very sudden with headache and pain at the back of the neck and across the shoulders, followed in about 12 hours by unconsciousness lasting three days, during which he was brought a seven hours' railway journey. He was fed by tube for seven days. Head retraction and Kernig's sign marked. Eventually gradual recovery commenced without any special features, and was complete in about five weeks from the onset of the disease.

The other cases of the same epidemic showed no features of special interest. The two cases that reached necropsy showed post-mortem findings similar to those in Case 2A.

One case that occurred in the same epidemic, in which, though the patient died before I saw him, there is very little doubt of the diagnosis, exemplifies very well another distinct type of the disease. The onset in a native of superb physique was very sudden with pains at the back of the neck and across the shoulders, and severe headache. Unconsciousness supervened in about an hour and a half, and death in six hours. At the post-mortem examination the only macroscopical feature was excess of cerebro-spinal fluid, which was removed from absolute clarity by the nearest possible turbidity. In none of these cases was any treatment, other than symptomatic, adopted.

I was told by my colleague, Dr. Nicholls, of the success of his prophylactic measures of burning down all the natives' huts occupied by those amongst whom his cases occurred, syringing out the nose and naso-pharynx with weak antiseptic of everyone exposed to infection, and causing them all to take a bath in a strong solution of cyllin, and immersing all bedding, clothes, &c., in a still stronger solution. I therefore decided to follow out the same plan of campaign, only instead of burning the huts I pulled them all down and left the corrugated iron sheets of which they were made lying under the powerful African sun for two days, and subsequently had them re-erected on a different site. The bathing of all the natives exposed to infection, together with their clothes, bedding, &c., in cyllin 1 in 400 and 1 in 200 respectively, was carried out, but owing to there being considerably over 500 natives to be dealt with, I omitted the nasal syringing on the theory that an antiseptic strong enough to kill the meningococcus will probably have a similar effect on the cells of the nasal mucosa, whereas one strong enough only to inhibit their growth will so injure the nasal mucosa as to render it even more unable to resist the attacks of the organism. The result of these measures, as of those of Dr. Nicholls, was absolutely successful, not a single case occurring amongst the natives in the vicinity until six months afterwards, when the second epidemic occurred amongst natives lately imported from a totally different source.

Second Series.

This epidemic, as above mentioned, occurred amongst natives employed as military porters, who had been for a month in Mombasa, and amongst whom, while in Mombasa, a few sporadic cases had occurred.

CASE 1B.—Aged about 14. Physique and general condition poor. Onset almost insidious, with mild headache, very slight stiff-neck, and slight pains in the limbs. These increased until, on the third day, the headache was very severe and the head retraction excessive. On the fifth day semiconsciousness supervened, with, at times, delirium, in which the patient was very restless, and, on one occasion, eluded his watchers and walked 400 yards before he collapsed. This condition continued for some eight days, during which wasting became excessive. Recovery commenced about the twelfth day, proceeded uneventfully, and was complete in about five weeks from the onset.

There followed five cases of no special interest, four of which died. These five cases showed a tendency for the disease to assume a more virulent type, as evidenced by the suddenness of onset, severity of general symptoms, excessive head retraction, shortened time before the onset of unconsciousness, and the rapidity of the occurrence of death. None of the cases that died had any treatment other than symptomatic. The one that recovered was treated with intramuscular injections of soamin, gr. 5, on alternate days, but only in the later stages of the disease when convalescence was well established—i.e., during the later stages of the epidemic, when I made the exhibition of soamin a routine measure.

CASE 2B.—Aged about 25. Physique and general condition exceptionally good. History of syphilis probable, but not very clear. Taken ill at 6 P.M. with severe headache, and pain in the back of the neck and back. The obtainable history is not very clear, except that he was obviously very ill quite soon after the onset. About 2 A.M. unconsciousness supervened, and continued without remission until death. When I first saw him at 9.30 the next morning he was deeply unconscious, with rapid stertorous breathing, and in a condition of absolute flaccidity, and presenting no sign of meningitis excepting the unconsciousness. The general aspect of the case was almost exactly like that of a severe cerebral hæmorrhage. The pupils were of medium size, reacting to light. No strabismus. There was absolutely no resistance to any passive movements of any kind. Fæces had been passed, the bladder was distended, necessitating the use of a catheter. Though I was naturally on the look-out for meningitis, I could not correlate this case with any known manifestations of that disease, and made a tentative diagnosis of cerebral hæmorrhage. The patient died at 11 A.M., 17 hours after the onset of symptoms. At the post-mortem examination I found thick, creamy, yellow pus involving the whole brain and spinal cord, especially abundant at the vertex. The ventricles were filled with turbid fluid, and the ependyma slightly injected.

The 10 or 12 following cases were of the ordinary acute or fulminating type, and betrayed a gradual though distinct tendency for the later cases to be of more virulent nature, both as regards the suddenness of onset, shortness of time before unconsciousness supervened, and rapidity of death. The average history would be sudden collapse of the patient while at his work, complaint of pain in the back of the neck and across the shoulders, and headache of varying intensity. In one or two cases the headache seemed to be almost absent, pain in the head not being complained of until quite late in the disease. In the earlier cases unconsciousness usually came on in the third or fourth day, and death in five to seven days, and in the later ones unconsciousness in from six to 36 hours, and death on the second to the fifth day. Head retraction, Kernig's sign, and general rigidity were present in all these cases; the abdominal and epigastric reflexes were always absent. No cases showed any material change in the tendon reflexes.

CASE 3B.—A case of the ordinary rapid type with unconsciousness on the third day and death on the fifth day. On the third day enormous quantities—several ounces—of thick yellow pus were discharged from the nose. In this pus I demonstrated the presence of intracellular diplococci.

CASE 4B.—A case of the rapid type with death on the third day. Unconsciousness supervened only about 10 hours before death. On the second day diarrhœa commenced, at first with the passage of fæcal stools; afterwards no fæcal matter was passed, but large quantities of mucus mixed with yellow pus. Unfortunately, I was unable to examine this pus microscopically.

CASE 5B.—Aged 22 or 23. Physique and general condition good. Sudden collapse while at work at 12 o'clock midday. Within half an hour the patient was unconscious, and died at 2 P.M. The post-mortem examination showed a slight excess of cerebro-spinal fluid, containing pus cells and intracellular diplococci.

At this stage, three weeks after the outbreak of the epidemic, the general run of cases showed a tendency to diminution of virulence according to the standards above set forth, while coma lasted a shorter time, and death became less inevitable.

CASE 6B.—The patient was of good physique, but the general condition was unsatisfactory. He came as an ordinary out-patient, complaining of headache. I found stiffness of the neck and a very doubtful Kernig's sign, and gave him a prophylactic dose of soamin, gr. 5. The next day he complained of pains in the arms and legs, and there was slight head retraction, and an undoubtedly positive Kernig's sign, together with distinct general muscular rigidity of the limbs. For three weeks the neuritic pains in the limbs continued, and he complained of girdle pains involving the trunk roughly from the dorsal roots 9 to 12, and I was able to demonstrate a band of hyperæsthesia involving the skin area of the same dorsal nerve roots. I could not find any anæsthesia. Weakness of the legs increased and eventually became excessive. The knee and ankle jerks were very weak, but could always be obtained with difficulty, but there seemed no doubt that the weakness of the legs, though largely due to the general condition, was to be partly accounted for by a definite myelitis involving the anterior cornua of grey matter of the lumbar region, or neuritis of the anterior nerve roots. Wasting of the muscles of the legs was very excessive.

At no time did this case show any signs referable to cerebral meningeal involvement, except for the very slight headache and almost negligible retraction of the head. Recovery was gradual but complete, the patient complaining of pains of a rheumatic type in the limbs for a fortnight or three weeks after the cessation of all active disease.

CASE 7B.—Almost exactly similar to Case 6B, except that the first symptom was neuritic pains in the limbs. The arms in this case were more involved than the legs, and there was indefinite hyperæsthesia over the chest. In this case there was rather more head retraction than in the last case, and a distressing feature was a very severe herpes labialis involving the upper and lower lips, and spreading outwards on either side of the corners of the mouth.

CASE 8B.—A case of mild type and slow onset. On the fourth day the temperature rose to 107° F., and I found signs of a slight broncho-pneumonic condition at the left base. The hyperpyrexia continued for three days with a temperature of from 105° to 107°, and the case ended in complete recovery.

CASE 9B.—This patient, aged about 17, was of very poor physique and general condition, and had been attending as out-patient for a month with chronic headache and a temperature of from 99° to 100° every day, to account for which I found nothing on physical examination. He eventually developed a Kernig's sign and head retraction. Eventual complete recovery.

I adopted the same prophylactic measures in this epidemic as were so successful in checking the first. On two occasions the bathing of the 800 natives implicated in cyllin 1 in 400, and their clothes, bedding, &c., in cyllin 1 in 200, was carried out. The camp in which they lived was twice moved, the corrugated iron, of which the huts were made, being at the same time exposed to the sun for two days. Isolation of contacts was, of course, carried out and a strict isolation of cases enforced. The hut in which any case had occurred was broken down and the iron composing it exposed to the sun for two days and all the huts had their roofs removed every day, so that the vertical sun could get at the interior. As a last despairing measure the camp was split into two separate halves, and each half into two sections, in the hope that one section might be declared free from the disease, but no good resulted, and the disease only died out when all the natives were returned to their own homes in a part of the country where cerebro-spinal meningitis is endemic and not epidemic.

The treatment adopted was in the main symptomatic, but in the later stages of the epidemic intramuscular injection of soamin, gr. 5, on alternate days was carried out on every case, both in the case of those in the acute stage and of those convalescent from the acute stage in the earlier stages of the epidemic. As regards these injections the syringe and needle were carried in a small tin filled with cotton-wool soaked with methylated spirit. The soamin was made up in a solution of gr. 1 in ♏ 5 of filtered water, sterilised by boiling, and kept in a small glass-stoppered bottle holding 16 doses. For use the syringe was removed from the spirit-soaked wool (a small piece of which was used to cleanse the patient's buttocks), the needle inserted into the bottle and the required dose drawn up into the syringe, and injected into the buttocks of the patient. If, as was almost invariably the case, another injection had immediately to be given, the process was repeated without further sterilisation, and though I gave upwards of 300 injections in this way, in no instance did any untoward symptoms occur.

Persons attacked.—It will be noticed in the cases which I have detailed above that in patients of strong physique and good general condition the onset was rapid and sudden, the attack severe, and death the rule, whereas the milder cases invariably occurred in the poorer specimens. The two most virulent cases that came under my notice were Cases 2B and 5B, and these were both natives of exceptional physique and general condition;

whereas the mildest case and the one showing the most insidious onset was in a patient of exceptionally poor physique and in a condition of very poor health for one month before he developed the disease. Doubtless, however, I failed to diagnose many still milder cases. This is an extraordinary and, I think, inexplicable feature of my cases, and one that held good, almost without reservation, throughout the two epidemics.

Conditions of bronchial catarrh were very common amongst the natives in whom the second epidemic occurred, amounting certainly to 25 per cent. of the whole number, but I have not been able, on looking over my notes, to correlate any special tendency for those so affected to be attacked by meningitis.

Incubation period.—I obtained no evidence to enable me to make any statement as regards this. Three weeks elapsed after the porters were brought from Mombasa to the highlands before the first case occurred, but his only serves to prove that someone must have carried the virus about with him for that period without showing any symptoms.

Prodromal symptoms.—I was unable to notice any constant prodromal symptoms. The disease usually attacked perfectly healthy individuals without any warning. In one case there had been low fever and headache from an unknown cause for nearly a month before meningitis became obvious, but this had probably nothing to do with the disease.

The Onset and Acute Stages of the Disease.

These may be divided into five general types or degrees of acuteness:—(*a*) Fulminating type, (1) exhibiting the ordinary symptoms of rigidity, &c., and (2) accompanied by coma so deep as to give rise to complete flaccidity; (*b*) acute type; (*c*) the common type, less acute than (*b*); (*d*) subacute type; (*e*) those cases in which symptoms of cerebro-spinal meningitis are practically or entirely absent; and (*f*) spinal type. These must not be taken as pathological, or even clinical entities, but merely as an attempt at classification and subdivision of the disease into the forms in which it is usually seen. For the purposes of description cases complicated by infection by the meningococcus of other organs than the meninges may be placed in a separate category as under (*g*) combined infection, (1) with rhinitis, (2) with conjunctivitis, (3) ? with enteritis.

(*a*) *Fulminating type.*—1. A very common form, of which Cases 3A and 5B are examples. The onset is very sudden, and in a few minutes the patient is completely collapsed. Unconsciousness comes on within an hour or two, but is never so complete that the general muscular rigidity is lost, though the irritability usually seen in meningitis is commonly absent. Death is almost invariable. 2. A rare form of which I have only seen one example—Case 2B. Diagnosis of this form is probably impossible except by the examination of the cerebrospinal fluid, as the clinical condition presents no resemblance to the commonly accepted picture of meningitis.

(*b*) The ordinary extremely *acute form*, in which the onset is sudden, with headache, pain in the back of the neck, and very frequently with pain across the shoulders, with or without the headache and pain in the neck. The patient is very ill within a few hours of the first symptoms, and coma supervenes in from 24 to 48 hours. The ordinary signs and symptoms of meningitis are always present, headache being always acute, head retraction often excessive, Kernig's sign strongly positive, and irritability continues throughout the coma.

(*c*) The *commonest form* is something between Type (*b*) and Type (*d*). The mode of onset is variable, ranging from practically the same thing as in Type (*b*), sometimes accompanied by rigor, to insidious headache, gradually intensifying, with pain radiating down the neck and across the shoulders. In other cases rheumatic pains in the limbs, and usually across the shoulders, are the first complaint. If the patient is examined in the earliest stages it will generally be found that there is resistance to anteflexion of the head, and if the head is forcibly rotated so that the head looks towards one or other shoulder, pain is complained of. A forcible depression, and at the same time forward movement of the shoulders, causes discomfort. Within 24 hours the nature of the case has usually become obvious by reason of the marked stiffness of the neck or even obvious head retraction, and the presence, to a greater or less degree, of spasm of the ham-strings, giving rise to Kernig's sign. This type of case usually becomes semi-unconscious, with continuance of excessive irritability and dislike to being disturbed throughout the acute stages of the disease, and in five to seven days is usually on the way to recovery. Sometimes in this type of case coma deepens, is protracted, and the patient dies from exhaustion or toxic absorption.

(*d*) *Subacute type.*—In this form onset is very insidious, usually with headache, and often with pains of a rheumatic type in the limbs, back of the neck, and across the shoulders. These may continue for several days before the persistence and increasing severity of the headache and occurrence of stiffness of the neck or head retraction give rise to suspicion of the true nature of the disease. The duration of the active stage is from seven to ten days, and complete recovery is the rule. This form is exemplified by Cases 6B and 9B.

(*e*) *Cases unaccompanied by the ordinary symptoms of meningitis.*—These are cases of a very mild type which range from Type (*d*) to those in which there are no symptoms, and the diagnosis rests on the demonstration of the meningococcus in the nasal mucus. In these cases at the extreme end of a long series of types of decreasing virulence, there is probably very slight or no infection of the meninges, the sole lesion being a meningococcal infection of the naso-pharynx. I probably encountered many such cases, but, owing to circumstances especially inauspicious for investigation, completely failed to recognise them.

(*f*) *Cases in which spinal symptoms predominate.*—These cases are obviously due to the predominating implication of the spinal meninges, whilst the cerebral meninges are comparatively little affected. Possibly there is a definite infective myelitis of the cord and neuritis of the spinal nerve roots, or in other cases these may be of toxic origin only. Cases 6B and 7B are examples of this type, different regions of the cord being affected.

(*g*) *Cases in which there is meningococcal infection other than that of the meninges.*—(1) *Rhinitis and naso-pharyngitis.*—This is probably of universal occurrence, to a greater or less degree, in every case of cerebro-spinal meningitis, and is probably the initial lesion. In certain instances, of which Cases 2A and 3B are examples, it becomes a marked feature of the case by reason of the excessive amount of pus discharged therefrom.

(2) *Conjunctivitis.*—This is probably caused merely through the accidental inoculation of the meningococcus on to the conjunctiva, or possibly it is an ascending infection from the nose *viâ* the lacrymal duct, and is of no special interest. Examples are quoted in Cases 1A and 2A.

(3) *Enteritis.*—In the absence of any positive evidence on this I can say nothing. The point is of importance in connexion with prophylaxis as regards the treatment of fæces, not so much in England, where the method of disposal of sewage prevents the desiccation and pulverisation of fæces, as in places where the earth system is the rule.

General Symptoms and Signs.

We have, therefore, in cerebro-spinal meningitis a disease varying widely in type, acuteness and severity. At one end of the scale it is a disease of such exceptional severity and acuteness that it can cause death in so short a period as two hours (*vide* Case 5B), and at the other end occur cases with possibly no symptoms, and in which the existence of a definite meningeal infection is improbable, though there is certainly a meningococcal nasopharyngitis.

I have already discussed, incidental to the description of cases, and analysis of the types of the disease, the common signs and symptoms of the disease. It remains, therefore, only to touch on one or two other points of interest.

Temperature.—In the average case this rises rapidly with the onset of symptoms to anything between 100° and 103°, and thereafter is very irregular until all active disease has ceased. In Case 6B, which I saw very early, almost before the signs of meningitis had developed, the temperature had already reached 100·2°. In one case (8B) the temperature rose to 107° and remained near that height for three days, but this case was not wholly uncomplicated, there being a broncho-pneumonic condition of the lungs at the same time.

The pulse.—This shows nothing characteristic. I was quite unable to verify the popular supposition that the pulse is comparatively slow in meningitis, as in every case the pulse-rate was in keeping with the height of temperature then prevailing.

Subcuticular hæmorrhages.—These were never observed, possibly owing, in some measure, to the black skin of the patients.

Ocular palsies.—These are said to be very common in meningitis. I, however, never saw them in any case of this series.

Optic neuritis.—I was debarred by general circumstances and the lack of a suitable lamp from making a routine examination of the fundi oculorum. (Not that I believe that it would be possible under any circumstances with the average raw native.) In no case during convalescence or on recovery was there any complaint of defective sight.

Treatment.

Dr. J. O. Shircore, of the East African Medical Service, has written a very able article praising the effect of intramuscular injections of soamin in meningitis. He claims that the drug is excreted into the cerebro-spinal fluid and there has a deterrent effect upon the growth of the organism, and he gives results of the examination of the cerebro-spinal fluid of cases before and after the use of the drug, from which he claims that its use caused degeneration of the diplococci. That may be so, but in the 35 odd cases that I have used the drug I have failed to notice any benefit from its use. Nor could I observe any difference between the general course of the disease in those cases in which it was used and those in which it was not used. Ordinary general treatment on symptomatic lines was adopted in all my cases.

Lumbar puncture I could not employ, for reasons explained above, though from previous experience of its use in cases of post-basic meningitis I very much doubt its efficiency as a therapeutic measure, saving insomuch as its good effect on headache and other pressure symptoms is undoubted.

Morbid Anatomy.

In all cases I found evidence of pyogenic infection of the meninges of the brain and spinal cord, and in all such as microscopic examination of the cerebro-spinal fluid was carried out the meningococcus was demonstrated. The fluid varies from the merest possible turbidity to thick, creamy, yellow pus. In one or two cases there was a preponderance of the pus at the base of the brain, but in the great majority it ascended well on to the vertex and descended into the greater fissures of the brain.

Neither of the cases that showed a preponderance of spinal symptoms came to necropsy, so that the question of the existence of a definite infective, or only toxic, myelitis and neuritis must remain unsolved.

The existence of thick pus in Case 2B, which died 17 hours after the onset of symptoms, is a little difficult to explain on pathological lines.

Cerebro-spinal Meningitis and Post-basic Meningitis, and the Development and Cessation of Epidemics.

The difference between these two diseases is an etiological rather than a clinical one, insomuch as the first is the epidemic form of the second. They are both caused by organisms morphologically identical, though differing in the physiological character of virulence.

Several sporadic cases of meningitis occurred amongst the same group of natives as supplied the second epidemic while at Mombasa, and since they left that place several further sporadic cases have occurred amongst others of their number who remained at the coast. When brought into the cooler climate of the highlands nearly three weeks elapsed before the first case occurred, the next case was two days after, another followed the next day, and thereafter cases occurred at the rate of about two a day for three weeks. On some days as many as four new cases occurred, on others only one. After the three weeks the rate of incidence gradually declined, until during the last week before the whole group of natives were returned to Uganda, and out of my care—i.e., the sixth week of the epidemic—only two fresh cases occurred.

Parallel with the rise and fall of case incidence ran the virulence and acuteness of the attacks. This was so well marked that I have no doubt that if it were plotted out there would be a definite and nearly regular curve showing the rise and fall of virulence of the virus.

I have no definite information on the point, but had the epidemic continued after their return to their homes where the disease is endemic I should certainly have heard of it, and so the two ends of the curve would indicate the point where sporadic post-basic meningitis merges into epidemic cerebro-spinal fever.

Magadi, British East Africa.

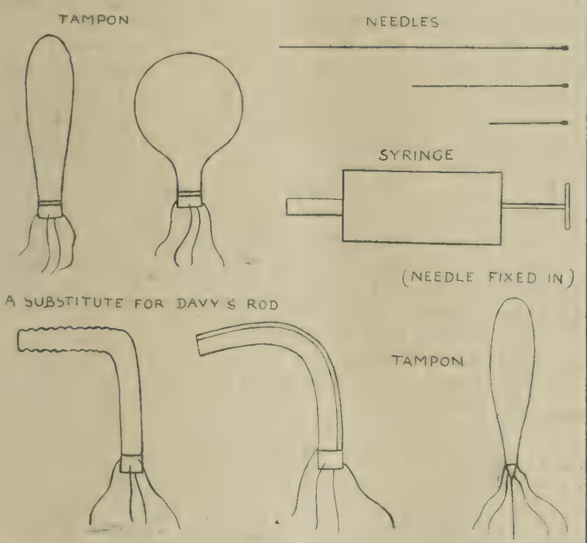
A TAMPON FOR CONTROLLING A SEVERED INTERCOSTAL ARTERY,

WITH OTHER POSSIBILITIES.

BY JOHN FURSE McMILLAN, M.R.C.S. ENG.,
CAPTAIN, R.A.M.C. (RETIRED).

ON one occasion, at Rawal Pindi, India, I experienced the mischance when operating on a case of empyema, the Dieulafoy's aspirator being unavailable, to nick the intercostal artery, whilst using the large trocar furnished in the military operating case. The recognised treatment then was, and seemingly now is, to plug the wound with a dossil of lint saturated with perchloride of iron, or, failing this, to resect a portion of rib and then to tie the severed, or partially severed, artery. But of course in peace time, and presumably also in war time, the occasion permitting, one would be very chary of tampering with the rib of a soldier, whereby a weak spot might be constituted.

Treatment by perchloride of iron in the present case was ultimately successful. But had I been near an instrument maker I would have had made a small tampon of stiff indiarubber of a fusiform shape such as is shown in the illustration. I would have inserted the collapsed round end into the pleural cavity, filled the tampon with water from the nozzle, and then having attached tapes to the stirrups, would have forcibly drawn the now swelled, rounded, hard, and solid indiarubber directly outwards, whereby such pressure would be made upon the nicked intercostal artery as to control it easily, whilst the affixing tapes to the chest wall by means of sticking plaster would complete the matter.



Such an invention or contrivance as the above has not hitherto been employed for the control of hæmorrhage where pressure can readily be applied to bone, and nowadays when operations are common for the treatment of bronchiectasis by ligature of branches of the pulmonary artery the possibilities of such a tampon would appear to be great. To instance: the needles shown, affixed to the nozzle and passed through a wound, should readily control the femoral artery in Hunter's canal; axillary; brachial; an artery lying on interosseous membrane; the subclavian, by passing the needle under the clavicle; branches of the facial and internal maxillary passed outwards from inside the mouth; as a substitute for Davy's external iliac compressing rod—in this case the indiarubber being of stouter substance and of the shape shown in the diagram. Again, the deep gluteal vessels might be compressed against the femur or ligaments; whilst run through the palm the deep palmar arch should be thus controlled without danger of sloughing, for with a water tampon the pressure will be evenly distributed, whilst the main point is backward pressure on bone by the forcible drawing of the tampon towards one.

Sandown, I.W.

THE PSYCHOLOGY OF

TRAUMATIC AMBLYOPIA FOLLOWING THE EXPLOSION OF SHELLS.[1]

BY J. HERBERT PARSONS, D.SC., F.R.C.S. ENG.,
OPHTHALMIC SURGEON, UNIVERSITY COLLEGE HOSPITAL, LONDON; SURGEON TO THE ROYAL LONDON (MOORFIELDS) OPHTHALMIC HOSPITAL.

OPHTHALMOLOGISTS have become familiar recently with cases of amaurosis and amblyopia resulting from the shock of the explosion of shells at the front. In many cases direct injury of such a nature as to cause definite organic lesion in the eye or visual paths can be eliminated. The earlier symptoms, which I have not personally observed, have been described and investigated by Dr. C. S. Myers, F.R.S.[2] The history of a typical case is briefly as follows.

A man after more or less prolonged fatigue, induced by marching and exposure in the trenches, is incapacitated by the explosion of a shell in his immediate vicinity. He may be merely knocked down or thrown into the air, and more or less seriously injured or wounded by concussion, shrapnel bullets, or shell splinters. Consciousness is lost for a variable time, but often not so far as to prevent automatic movements, so that the man may walk in a dazed condition to a dressing station. The mental equilibrium at this stage is much disturbed, and all memory of this phase is usually lost. The most striking feature of the case is that the man is instantaneously struck blind. The blindness may be associated with deafness, loss of smell, and loss of taste, but all these are less frequent than the blindness. On examination it is found that there are intense blepharospasm and lacrymation. The lids are opened with great difficulty and examination of the eyes is almost impossible. I am not aware of any record of the condition of the pupils at this stage. In the course of a week or two the blepharospasm diminishes and it becomes possible to examine the fundi. Of course, there may be local injury to the eye, but in uncomplicated cases the eyes are found to be normal. The pupils react to light, though in some cases the reactions are sluggish, and sometimes one pupil differs from the other, being larger, or more sluggish in its reactions. The fundi appear to be absolutely normal. By this time probably some restoration of sight has occurred. Light is perceived and large objects may be distinguished. As improvement occurs the patient manages to grope about, usually with his hands outstretched before him, but it is noteworthy that he does not usually stumble up against objects in his path. As soon as it is possible to take the fields of vision it is found that they are markedly contracted, and that indeed to a degree which seems scarcely consistent with the avoidance of obstacles in walking.

---

[1] A paper read at the Neurological Section of the Royal Society of Medicine on March 25th, 1915.

[2] THE LANCET, Feb. 13th, 1915, p. 316.

The recovery of vision is slow, but eventually it seems always to be complete. In the later stages I have had cases in which the right eye is more affected and recovers more slowly than the left. It may recover to the extent of having only a central scotoma, though this may reduce the visual acuity to 6/60 or less. By perseverance and encouragement the patient may be induced to read a few lines of the types, and I have had cases where the manipulation of weak plus and minus lenses has led to the full 6/6 being read.

Now there are several suspicious symptoms in many such cases. The eye to recover last is often the shooting eye. Some patients show an obvious disinclination to return to duty. Some candidly admit to being in a "blue funk." In all there has been a complete mental upset, sometimes accompanied by hysterical symptoms—outbursts of weeping, &c.—in the early stages. These features render it only too easy to jump to the conclusion that there is often a large element of shamming in the case. It is because there is very grave danger of cruel injustice being done to men who have faced the music and come battered out of the ordeal that I wish to attempt an explanation of the underlying psychology.

In the first place it is necessary to segregate these cases from allied conditions due to organic lesions or to malingering. It is not always easy to eliminate organic lesions of the type which causes so-called retrobulbar neuritis. It is still less easy to eliminate malingering, but as this depends upon a knowledge of the psychology of the individual it forms a prime object of the following discussion.

Since there is no demonstrable organic lesion these cases may be regarded as examples of injuries or wounds of consciousness. This does not imply that there is no neural lesion to account for the psychological disorder, but merely that it has hitherto escaped observation. Without entering into a disputed question, which is largely metaphysical, we will adopt the view of parallelism between physiological neural processes and psychological events or changes in consciousness.

As regards cases of the type to which the group under consideration belongs, it may, I think, be admitted that the disorder of the conscious processes varies with the nature and severity of the injury and with the organisation of the individual's character. Of these the latter is by far the more complex, and in order to make my meaning clear it will be necessary as briefly as possible to sketch the evolution of character. In doing so I shall be guided chiefly by the deductions of such writers as C. Lloyd Morgan, J. Mark Baldwin, and William MacDougall, whose extraordinarily suggestive work does not seem hitherto to have been sufficiently brought to bear upon pathological problems.

Mental evolution may be divided into three stages, which may be called the sentient, the conscious, and the ideational. The sentient stage is exemplified in those organisms which show simple reflex response to stimulation. In the lowest stage of all, such as the amœba, the three parts of the reflex arc, the afferent, central, and efferent, are not anatomically differentiated. Organic evolution is accompanied by anatomical complexity and correlation of reflex arcs. The conscious stage is exemplified by those animals, such as birds and lower mammals, in which complex and compound reflexes have become organised into instincts; mere sentience—as we may call it, for we can have no knowledge of what this lowest grade of consciousness really is—gives place to consciousness which is limited to the perceptual plane. The mind of such an animal is conscious only of the percepts derived from concrete objects. It reacts to these primarily in an instinctive manner in accordance with inherited instincts, the motor responses varying according to the species. In addition, however, it has acquired the ability to modify these motor responses in the light of experience. In other words, it is capable of controlling and modifying its instinctive reactions by intelligence. In the highest stage, which is reached so far as we know only by man, consciousness is raised to the conceptual plane. The animal has acquired the ability to think in terms of abstract ideas and to form rational judgments.

Animal life possesses one all-pervading feature, the capacity for and manifestation of movement, and from one end to the other of the scale the movements are teleological or purposive. It is for the metaphysicians to explain—if they can—why a merely sentient organism manifests purposive movements when it is inconceivable that it can in any sense have knowledge of the end which will be ultimately attained. Indeed, it would be a bold assumption that such is really the case if it were not unexceptionably proved that at a higher level many lower animals perform the most complicated instinctive actions for an end—often the preservation of the species—which it is quite impossible that they can foresee. Movement entails wear and tear of protoplasm, no matter how lowly it be, so that the fundamental teleological factor is the search for food, and biological necessity demands the preservation of the species. Hence the behaviour of the lowest organisms is directed to two ends, nutrition and reproduction.

The simple reflex is a purposive response to stimulation. The stimulus sets up an afferent impulse which acts upon a central mechanism. The motor response is determined in the centre by the nature of the afferent impulse, and in its simplest form is a positive or negative taxis.

The simple instinct, compounded of complex reflexes, shows a similar tripartite nature, afferent, central, and efferent. The afferent impulses so modify the central mechanism as to give rise to an affective state in consciousness. This state is an emotion. It in turn gives rise to a definite and specific conation or striving to a particular end. The conation manifests itself in motor activities all designed to attain that end. In so far as the end is attained the emotion is satisfied and a pleasurable feeling is experienced; in so far as the end is thwarted, dis-pleasure is experienced, and this usually reinforces the conation until eventually the end is attained.

MacDougall enumerates the following primary instincts and emotions of man: the instinct of flight and the emotion of fear, the instinct of repulsion and the emotion of disgust, the instinct of curiosity and the emotion of wonder, the instinct of pugnacity and the emotion of anger, the instinct of self-abasement (or subjection) and of self-assertion (or self-display) and the emotions of subjection and elation (or negative and positive self-feeling), the parental instinct and the tender emotion, the instinct of reproduction, the gregarious instinct, the instinct of acquisition, and the instinct of construction. To these are added certain innate tendencies—sympathy, suggestion, imitation, and so on.

In addition to the afferent impulses received from external stimuli, others are received from internal organs. The sum total of the normal impulses determines the obscure background of consciousness (cœnæsthesia) on which the general tone of mental life depends. The *disposition* of an individual depends upon the sum of all the innate instincts with their specific conative impulses. The *temperament* depends upon the influences exerted on the nervous system and through it on mental process by the functioning of the bodily organs, and on the general functional peculiarities of the nervous tissues.

In lower animals the emotions are probably generally experienced in unmixed forms. In man they tend to become combined in organised systems each centred in some object. These organised systems are the sentiments (A. F. Shand), of which love, hate, and respect are the types. Admiration, awe, gratitude, scorn, contempt, envy are complex emotions which do not necessarily imply the existence of sentiments. Reproach, jealousy, resentment, revenge, shame, remorse, sorrow, pity imply the existence of sentiments directed towards some object. "It is only through the systematic organisation of the emotional dispositions in sentiments that the volitional control of the immediate promptings of the emotions is rendered possible. Again, our judgments of value and of merit are rooted in our sentiments; and our moral principles have the same source, for they are formed by our judgments of moral value" (MacDougall).

Further, moral conduct is essentially social conduct. Psychology has been revolutionised in recent years by the writings of William James, G. F. Stout, and others, who have thrown into relief the previously well-nigh disregarded fact that the development of the individual mind cannot be explained by isolating it and examining its workings by introspection alone. Each mind is endowed with innate properties; these show inherited variations which cause one mind to differ from another. But in addition to this each mind is subject to acquired modifications due to its environment, and the most important element in its environment is the group of other minds with which it is brought in contact. Advance in moral conduct and the development of *character* are brought about by the growth of self-consciousness and of the self-regarding sentiment. The idea of self and the self-regarding sentiment are essentially social products, so that the complex conception of self ultimately attained is always of self in relation to others. MacDougall distinguishes four successive stages in the development of conduct: (1) the instinctive stage modified only by the experience of pain and pleasure; (2) the stage of control by rewards and punishments; (3) the stage of control by anticipation of social praise and blame; and (4) the stage of regulation according to an ideal of conduct.

Such, in the sketchiest outline, is the mental evolution which culminates in the individual character. The analogies which have been arduously elicited from comparative psychology are very illuminating, but they must not be pressed too far. It is true that in physical development the individual rapidly recapitulates the chief stages of the history of the development of the species, but this is true only in a broad sense, and can only be proved of any detail by direct observation. Similarly in the mental evolution of the child, so ably studied by Preyer, J. M. Baldwin, and many others, an instinctive phase resembling that of lower animals, an animistic stage resembling that of primitive races, and so on, may be dimly indicated, but it is doubtful if a baby ever exhibits a complete yet unadulterated instinctive response.

Underlying the psychological development outlined above there is a physical neural development, in which the tremendous stride which the human species has taken beyond the anthropoid ape is most obviously shown in the enormous development of the pallium. The development of the cerebral cortex, however, has not taken place without the most extensive rearrangement of lower structures. Cerebral control does not mean simply control of unaltered units. It means also modifications in the units themselves—modifications in reflex and instinctive responses both in kind and degree.

To sum up this long but necessary preamble, in the cases under consideration we are dealing with individuals of various moral and psychological character, disposition and temperament. Their temperaments are determined chiefly by the condition of their visceral organs and circulation. Their dispositions are determined by the sum total of the conative impulses of certain primitive instincts which vary within relatively narrow limits in their innate characteristics and relative strengths, and are subject to acquired modifications in accordance with the environment of the individual. Their characters are determined by their temperaments and modified innate dispositions, of which the latter are subject to a volitional control which varies according to the social environment and educative experience.

In the evolution from stage to stage through the phases reflex, instinctive, and ideational the earlier stage is not lost, but is made to subserve the new conditions. Thus in the most highly developed species, man, all persist. The earliest or reflex stage persists in the lowest anatomical and physiological level. It can hardly be doubted that the highest is a function of the most recently and highly differentiated part of the cerebral cortex. Whilst, however, we may say that the reflex mechanism is specially associated with the lower—segmental—region of the central nervous system, stretching from the mid-brain to the end of the spinal cord, owing to the elaborate rearrangement of structure and function which has occurred, it is at present impossible to localise with any degree of precision the neural bases of the higher instinctive and ideational processes. Their complexity is largely, though by no means wholly, a matter of correlation and association; and the anatomical basis of an isolated physiological function is to be sought rather in a unified system of widely spread neuronic paths—afferent, associational, and efferent—than in any so-called "centre."

It is further to be noted that the subservience of the more primitive phases of evolution is associated with what may be described as subservience in consciousness. Afferent sensational impulses, modified by afferent visceral impulses and by other more subtle impulses due to previous experience, lose to a large extent their specific characters and become merged in a complex cognitive impulse. Even from this the mind springs forward as it were to the emotional state which is thus aroused and becomes concentrated on the efferent conation. Consciousness is focused on the appointed end; all else is relegated to a subconscious background.

The effects of an intense emotional shock on this highly complex system may, *a priori*, be expected to be manifold and complex. Let us consider the effects of a blinding flash of light. In the first place it will produce certain definite reflex results—sudden closure of the eyes, retraction of the head, perhaps recoil of the whole body, and so on. Actual damage may be done to the delicate retinal structures, resulting in temporary or permanent defect of vision. But apart from these effects, the strong light stimulus will have other far-reaching results. Sudden and unexpected visual sensations play an important part in the sensational complex which gives rise to the emotion of fear. They are less potent, as a rule, in this respect than auditory stimuli. Nevertheless, they arouse an emotional state which varies from mere surprise to actual fear. Doubtless the natural instinct of flight is suppressed in the adult by the intervention of the self-regarding sentiment and manifests itself only in a sudden start. If the blinding flash is accompanied by a loud noise the emotion of fear is still more powerfully aroused. If also accompanied by an offensive smell the emotion of disgust is aroused and gives rise to repulsion.

The response of an individual to such a shock depends, therefore, essentially upon the degree of development of his self-regarding sentiment. As we have seen, this depends upon his disposition—i.e., the sum of all his innate instincts, his temperament, and the modifications and control which these have acquired as the result of his environment and experience. We cannot, however, isolate the sensational complex which causes the shock from the concurrent circumstances. The response will vary also according to these conditions—e.g., according to whether the individual is alone or one of a crowd, and so on.

In the case of a soldier under shell fire the conditions are unique. The man is usually bodily fatigued, whereby his control is impaired. He has "the fear of death before his eyes" and is in a state of acute excitement, whereby his normal judgment is impaired. These conditions conspire to give his innate instincts ungoverned play. On the other hand, positive self-feeling, aided by suggestion and imitation and the sentiments of patriotism, the honour of the regiment, his own honour, and so on, enforce his volitional control. At last, however, the shock comes which strikes him unconscious. It is not to be supposed that he is thereby anæsthetised to these emotional storms. It is rather to be conjectured that he is rendered "subconscious," and hence the more a victim of his lower instincts. This view is supported by the emotional behaviour of the men in the early stages, and by the fact that many of their actions can be revived by hypnosis.

The "unconsciousness" in these cases is to be explained physiologically by an abrogation of the functions of the highest level cortical cells. Recovery shows that the cells are not irretrievably damaged, and it is most likely that the block occurs on the afferent paths at the synapses of these cortical cells. Consciousness returns but there is blindness. So far as objective evidence goes the lower visual paths are intact and function normally. The optic nerves carry their impulses, at any rate as far as the pupil reactions are concerned. The condition resembles uræmic amaurosis. I have seen it also in children after post-basic meningitis. The block is somewhere above the so-called primary optic centres—external geniculate bodies, optic thalami, and superior colliculi. It, too, is probably in the synapses of the cortical cells, in this case the synapses of the fibres of the optic radiations. Sometimes such a block occurs physiologically and it is probably to be explained in the same manner. Everyone knows what may happen when reading an uninteresting book whilst the attention is diverted by some other train of thought. A paragraph is read and one suddenly becomes conscious of the fact that nothing has been conveyed to the mind. Yet on reading it again one may recall certain sentences as undoubtedly having been read though they failed to reach the fully conscious mind. Perhaps the suppression of the image of a squinting eye is to be explained in the same manner.

It is definitely stated by Dr. Myers that smell is partially lost in spite of the fact that there is no unpleasant odour noticeable when a shell explodes. This is probably to be explained by suggestion. I do not, however, think that it is necessary for the explanation of loss of vision and hearing that the visual and auditory paths respectively should have been definitely stimulated. These paths—situated in such intimate relation with the higher levels—play such a prepotent part in cerebral processes—equilibration, spatial percepts, and so on—that at any rate a partial visual block might be expected at times to persist beyond the recovery of consciousness. The duration of such persistence, however, is likely to be much greater if the primary shock has a powerful visual element, whether it be a blinding light or an awe-inspiring spectacle.

Though in the cases under special consideration there can be little doubt that the early loss of vision has a definite neural basis, it must, I think, be conceded that in the later stages the neural basis is of that undefined nature which we associate with so-called "functional" conditions. In other words, it is neurotic, but it is not "shamming," difficult though the line be to draw between them. I have had one case in which the vision of the left eye improved to 6/6, while that of the right improved to 6/36. By manipulating various glasses I succeeded in making the patient read 6/6 with + 0·5 D. sph. and − 0·5 D. sph. before the right eye and + 6 D. sph. before the left. He had the chance of taking a commission and was eager to do so. I feel convinced in my own mind, from his character and demeanour, that he was quite honest.

It has already been mentioned that in the earliest stage of recovered consciousness volitional control is almost or quite abrogated. The man is merely an emotional animal, or rather worse, for he is deprived of that intelligent control which plays such an important part in animal life. His behaviour is hysterical, but it is a passive hysteria, unlike the commoner active hysteria in which the partially emancipated emotions are often guided by some preponderant ideational impulse. There can be little doubt that in this stage the most potent of the primæval instincts—fear—holds almost undisputed sway, irrespective of the normal character of the individual, for the loss of volitional control implies the loss of the coördination of all those complex factors which make up the character of the man. As recovery progresses the outward manifestations of fear are more and more masked or suppressed, for the self-regarding sentiment gradually again becomes restored.

Its restoration, however, will be in accordance with the innate dispositions of the individual. If he is naturally mean-spirited it is unlikely that his self-regarding sentiment has developed beyond the stage of merely masking an ever-present pusillanimity; his motive power is limited to a sense of shame. If he is naturally of a fine character his fears will be suppressed with ever-increasing vigour as he becomes more and more conscious of the ideals of conduct which have shaped his character. In this stage of struggling to regain control the patient is at a disadvantage, and the acute observer will have the best opportunities for studying his springs of conduct. There are rare characters in which the emotion of physical fear appears to be non-existent, but in the vast majority of cases it is present, and however cleverly it is masked or however nobly it is suppressed it has to be reckoned with. If merely masked it will prove a very powerful incentive to the avoidance of renewed exposure to danger, and a temporary disability may give place to deliberate fraud. If suppressed it may yet require all the help which can be derived from the highest sentiments, reinforced by suggestion and by the active sympathy of discreet friends and advisers. These may all fail, but if so it is a case for pity and encouragement rather than contempt and obloquy.

It appears to me that these are the principles which should guide the medical adviser in his investigation and treatment of the case. We are accustomed to take the past histories and present conditions of our cases. In these "wounds of consciousness" the past history involves a difficult investigation of the innate dispositions and propensities of the individual, the environment to which he has been subjected in his home life, his school life and his further career, and last, but not least, in the special cases under consideration—the motives which led him to join the colours. For every man who enlists is not necessarily a ready-made hero. Many have enlisted merely because they are ashamed of not following the example of their friends. All honour to them; but they are not equipped with the sterling qualities of the man who is impelled by a noble ideal. The latter may recover completely from the shock, reinforced, indeed, by the sense of a moral victory won. The former may remain partial wrecks, too fearful of a renewal of their terrifying experience to be of any use in the fighting line. By injudicious forcing they may be wrecked entirely. On the other hand, by carefully studying their habits and tastes they may be switched off into other paths which will lead to the restoration of self-esteem and make them again useful members of society.

The investigation of the present condition is simply psycho-analysis in the true sense of that much-abused term. Amongst the many instincts and sentiments which have been enumerated and which will require to be studied and weighed, the sexual instinct will hold its proper, and no more than its proper, relationship. It cannot be ignored, for it is at the foundation of the parental instinct, the tender emotion, and the sentiment of love. As such it is potent for good or evil, and it is the physician's part to utilise it for good as far as may be, and above all not to frustrate that end by his own indiscreet probings.

As Dr. Myers has shown, hypnosis may be valuable in reconstructing the history. I am doubtful as to its use as a method of treatment, but others are better qualified to judge on that point. As regards therapeutic measures, it should be remembered that fright causes great exhaustion of the suprarenal glands.

I have restricted my remarks to a special type of so-called traumatic neurosis, but it is obvious that the principles which have been discussed are capable of wide-reaching application.

HETEROLOGOUS TRANSPLANTATION: MOUSE TUMOURS IN RATS.

BY W. E. BULLOCK, M.D. EDIN.,
ASSISTANT, IMPERIAL CANCER RESEARCH FUND.

WHEN a tumour arising in one species of animal is inoculated into an animal of another species the tumour fails to grow progressively. This specificity has in some cases been found to be so marked that a tumour occurring in one variety of mice will not grow in another variety. Throughout the literature of the experimental investigation of cancer there may be found repeated references to these facts, which must be taken into consideration in any theory of cancer. J. B. Murphy[1] has shown, however, that rat and mouse tumours may be grown by inoculating developing chick embryos. The inoculation is made on the fifth to the eighth day of incubation. The transplanted tumour fragment grows vigorously up to about the seventeenth day and then begins to be absorbed. Thus we have here a remarkable and conspicuous exception to the rule of specificity already noted.

It has been shown by Rywosch[2] that chick embryos have practically no bactericidal or bacteriolytic powers; and, *a priori*, one would suppose that the explanation of the success of the transplantation of rat and mouse tumours to chick embryos is to be found along similar lines—namely, the absence in the developing chick of the mechanism by which resistance to tumours of a foreign species is produced. The phenomenon has also been explained by assuming that the embryo contains an excess of "growth substances" which are not yet differentiated and which can thus provide sufficient of these necessary materials for the proliferation of the tumour cells.[3]

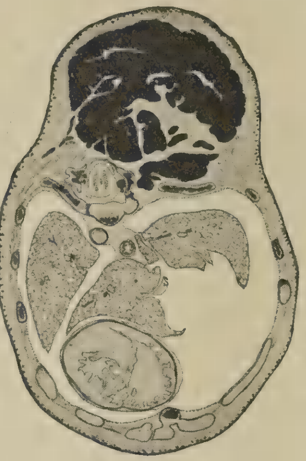
It seemed reasonable to anticipate that the mammalian embryo will provide as suitable a host for a tumour of another mammalian species as the more distantly related chick embryo, and it is with this possibility that the present paper deals. A brief outline of the work has already been given in July, 1914, in the Twelfth Annual Report of the Imperial Cancer Research Fund.

The technique by which developing chicks are inoculated is very simple, but the difficulties of inoculating mammalian embryos through the uterine wall without bringing gestation to an end are very great, though it has been done.[4] It was therefore decided first of all to inoculate new-born rats with mouse tumours. It is to be noted that when a freshly hatched chick is inoculated with a rat tumour the tumour fails to grow, and it might be thought, by analogy, that a mouse tumour would not grow in new-born rats. But this was found not to be so.

The rat, under 24 hours old, is inoculated by the needle method, preferably in the subcutaneous tissue of the back. Occasionally the needle strikes a vein and a fair amount of blood is lost, but only one animal in several hundred was killed by the actual inoculation. The transplantation must be carried out quickly and the animals must be kept warm. The chief difficulty in this work lies in rearing the young rats. The mother is very liable to kill her young after they have been interfered with, but these accidents may be very much reduced by handling the mother rat frequently during the period of gestation.

The tumours inoculated were a polymorphous sarcoma (37), a carcinoma (63) which in mice grows progressively until it kills the host, and a carcinoma (206) which grows for about 16 days and then disappears, leaving the mice in an immune condition. With each of these tumours it was found that rapid growth takes place in rats inoculated during the first day of life for from 10 to 17 days, the tumour then disappearing, as illustrated in the charts reproduced. (Charts A, B, C.) From a dose of 0·01 c.c. it is easy to obtain in 10 days a tumour weighing over 1 gramme. (Fig. 1.) The mass consists of healthy tumour cells, showing in microscopical sections their characteristic shape and arrangement, with numerous mitotic figures. After the tenth to seventeenth day increasing numbers of fibroblasts grow in thick strands from the capsule into the tumour, the tumour cells becoming necrotic. Eventually in a further period varying from one to two weeks the whole tumour is absorbed.

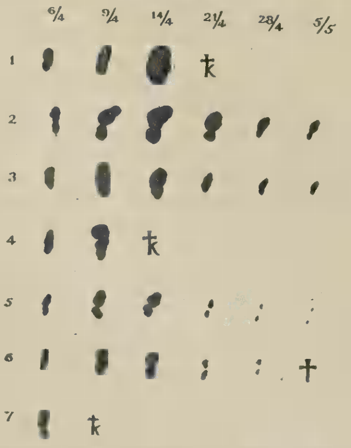
FIG. 1.



Section through the thorax of a young rat 17 days old, bearing a mouse sarcoma. The tumour (black) is penetrating between the spine and the muscles. Small areas of necrosis and bands of fibroblasts are found in the tumour; in the healthy parts of tumour mitoses are numerous.

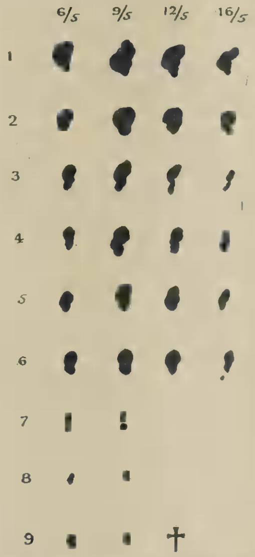
With regard to the sarcoma it was found to differ om the carcinomata in that it grows very well also in half-grown and adult rats. Russell[5] has shown that the cells of a mouse carcinoma survive and multiply in the normal adult rat for nine days; but the extent of this growth is insignificant compared with what has been obtained from minute grafts of the polymorphous sarcoma (37). Chart C indicates the size of the tumours obtained with doses of 0·02 c.c. of this sarcoma.

CHART A.



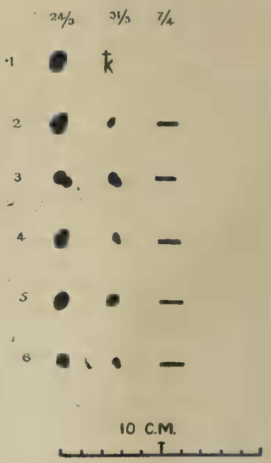
New-born rats inoculated on 30/3/14 with mouse carcinoma (63); dose 1·01 c.c. Scale as in Chart C.

CHART B.



New-born rats inoculated on 29/4/14 with mouse carcinoma (206); dose 0·01. Scale as in Chart C.

CHART C.



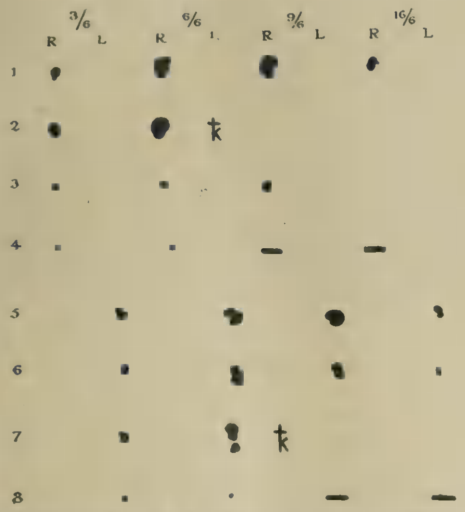
Half-grown rats, average weight 60 grammes, inoculated 17/3/14 with mouse sarcoma (37); dose 0·02 c.c.

The attempt has also been made to cultivate this sarcoma in series both in new-born and in half-grown rats. In the former case the attempt was partly successful; the tumour was maintained 49 days for five generations in rats, and was then lost through the mother eating the young animals. The growths of the third and fourth generations were, however, smaller than the first and second. This want of complete success was certainly due in part, if not altogether, to the difficulty of obtaining a regular supply of animals of suitable age, and to the frequency with which the mother rats killed their young.

When a tumour which has been kept growing in a succession of rats for as long as 46 days is again inoculated into mice it grows as vigorously as the tumours which have never been grown in rats. In other words, it is not modified by change of "soil"; the tumour cell is killed outright more readily than it is changed in character. It does not seem possible to cause the tumour to adapt itself to its new species of host so completely as to lose its capacity to grow in the species in which it arose. This practically amounts to saying that a mouse tumour cannot be converted into a rat tumour any more than a mouse can be converted into a rat. In the experiments in which the attempt was made to grow sarcoma (37) in half-grown rats, the tumour failed at the fourth inoculation, the growths becoming progressively smaller. Altogether the tumour was kept growing for 22 days in three generations.

One of the most interesting of Murphy's discoveries in his work with chick embryos is that the inoculation of a fragment of adult fowl spleen or bone marrow prevents the growth of a rat tumour inoculated simultaneously.[6] The addition of spleen or, to a less extent, of bone marrow enables the chick to resist the growth of the tumour cells. These experiments have been repeated with young rats, using spleen taken from a healthy adult rat. Half a litter of eight new-born rats were inoculated in the right axilla with 0·01 c.c. of an emulsion of mouse carcinoma (63); the remainder were inoculated in the left axilla with the same dose of the same tumour and in the right axilla with 0·01 c.c. of rat spleen. The growths obtained are represented in Chart D, which shows that the spleen has had no effect on the growth of the tumour. The same experiment was carried out with sarcoma (37) and with carcinoma (206), with similar results. It is probable, therefore, that the mechanism of the production of resistance in chicks to a tumour of a foreign species is different from that in young rats. The change from the new-born to the adult condition must take place fairly rapidly, as young rats a few days old already inhibit to a marked degree the growth of most inoculated mouse tumours.

CHART D.



New-born rats inoculated with mouse carcinoma (63) and with spleen obtained from an adult rat; doses 0·01 c.c. (*a*) Animals 1 to 4 received tumour in right axilla. (*b*) Animals 5 to 8 received tumour in left axilla and 0·01 c.c. of spleen in right axilla. It will be noted that no difference is observable in the amount of growth in (*a*) and (*b*). Scale ▬ in Chart C.

The temporary growth and ultimate disappearance of mouse tumours in new-born rats do not differ essentially from the results of similar inoculations into adult rats. In them also temporary growth, often only recognisable on microscopic examination, precedes the rapidly ensuing arrest of growth and absorption of the foreign tumour cells. Bashford and Russell[8] have shown that this disappearance follows on the development of an active immunity. If baby rats in which tumours of considerable size have developed and been absorbed be re-inoculated with fresh mouse tumour, it is seen that they are immune in the same way, and the sequence in the new-born rat only differs from that in the adult in the relative proportions of the two stages of growth and absorption. There is no valid reason to assume a different cause for the ultimate disappearance in the two cases, and the actively immune condition which has been demonstrated in both suffices to account for it completely. The disproportionate amount of growth obtainable in new-born rats is in all probability due to a failure, or rather delay, in the process of active immunisation. It must not be forgotten, however, that young animals are in general more suitable for tissue transplantation than old. Propagation in series is in consequence possible in very young animals by taking advantage of the rapid growth that occurs in the period which precedes the development of inimical substances. The success which has attended the attempts of several investigators to cultivate mammalian tumours and normal tissues *in vitro* in the plasma of alien species also points in the same direction, as in these circumstances the cellular elements responsible for the development of immunity are absent.

The results of these experiments are mainly of importance because of the analogy they present to the much more obscure process of immunity production by mice and rats to transplantable tumours arising in individuals of their respective species. This analogy is not very close, but it is instructive to note that Russell[7] has shown that those propagable tumours which grow progressively do not produce resistance to a subsequent inoculation. In alien species, however, even the strains which grow without inducing resistance in their own species exhibit only temporary growth and induce active immunity. The experiments will be continued, and the discussion of their bearing on this and other aspects of the cancer problem is reserved for a later date.

CORONERS' SOCIETY OF ENGLAND AND WALES.—Dr. F. J. Waldo, H M. coroner for the City of London, was elected President of the Coroners' Society of England and Wales at the annual meeting in London of the society on March 23rd. In returning thanks for the honour done him, Dr. Waldo reminded members that the founder and first president in 1846 was Mr. Serjeant Payne, a leader and reformer among coroners. He was president for 26 years, till his death in 1872. The first secretary was Mr. Langham. Both these gentlemen were predecessors of Dr. Waldo as coroners for London before the administrative County of London came into being. Succeeding presidents were Sir John Humphreys, coroner for Middlesex, and his successor, Dr. Danford Thomas, who had done so much for the improvement of coroners' courts, mortuaries, and post-mortem rooms, still so badly wanted in the country. Another strong coroner, he said, was Thomas Wakley, Founder of THE LANCET, and coroner for Middlesex, who successfully fought the justices at quarter sessions in their refusal to pay the rightful fees of coroners for what they (the justices) alleged were unnecessary inquests. Mr. Wakley brought in the Coroners Act of 1860, whereby county coroners were paid by salary in place of fees. Dr. Waldo said that the object of the Coroners' Society was to foster coöperation between coroners, to aid them in the more effective discharge of their duties, and to maintain their rights in the public interest. He promised to do his utmost to uphold the dignity of the coroner's court and the status, privileges, and rights of the coroner.

FURTHER OBSERVATIONS ON

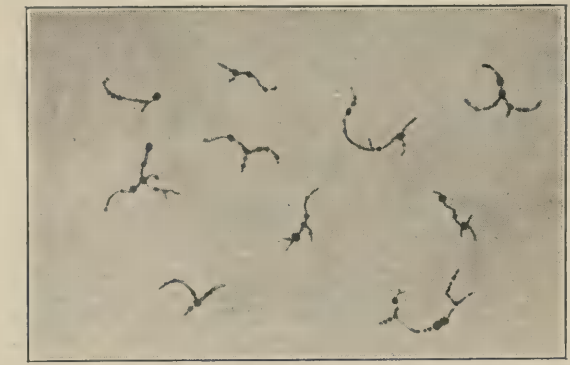
SPERM OIL TUBERCLE BACILLI: THEIR BIOLOGICAL SIGNIFICANCE.

BY A. H. MILLER, M.A., M.D. CANTAB., M.R.C.P. LOND.,
JOINT PATHOLOGIST TO THE SALFORD ROYAL, MANCHESTER CHILDREN'S, AND MANCHESTER NORTHERN HOSPITALS.

CERTAIN changes in the tubercle bacillus were described by me last year.[1] I here wish to go over some points previously mentioned and to bring forward some new matter.

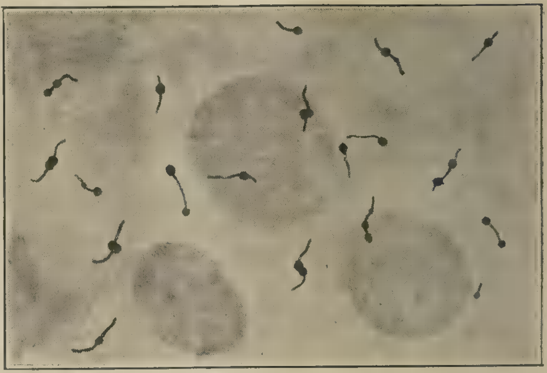
The percentages employed in the article mentioned and in the present one are empirical; other percentages may do as well or better. More recently the crude sperm oil has been used. The organism on the crude oil seems to grow better and more quickly on it than on the refined oil. There does not appear at the present time to be any essential difference between the two as regards either the loss of power of the organism to stain with carbol-fuchsin or the formation of granules, except that by the improved growth of the organism these two conditions take place more readily. If, however, the original culture of tubercle bacilli, to give them their common term, growing on the ordinary solid media is at all old, or growth is sluggish when subcultured, they will probably not grow at all, or only very slightly, when placed on the oil media. For the oil media the bacilli must be known to be actively growing. With actively growing bacilli there is often a definite moist growth in about 12 days' time, but the bacilli themselves are apparently no different from those obtained from the usual sources. It takes a further period of from three to four weeks before the changes described begin to become visible.[2]

FIG. 1.



A three-months-old culture, stained with carbol-fuchsin and washed. Not decolourised. 1/12 in. lens, No. 5 ocular. × 1500. Figs. 1 and 2 drawn by J. M. Manby.

FIG. 2.



Oil bacilli after passage through guinea-pig. From a two-months-old growth on 5 per cent. refined oil and 6 per cent. glycerine. Stain, Zeihl-Neelsen. The non-staining portions of the rods are not shown in the figure. × 1500.

The term "beading" that was used in my former communication is not an accurate description of the organism in all cases, especially in its earlier stages and with the lower percentages of oil (2·5), for the staining parts and the non-staining parts of the organism are then often in the form of definite long segments. Later, when with the richer oil mixtures the granules begin to develop and the segments to become broken up, the term "beading"[3] is perhaps better. It is not my purpose here to go into the earlier stages of the organism, the lower percentages of the crude oil have not yet been tried, but to bring forward the late results of growth on 5 per cent. mixtures of the crude oil[4] and some of the results of animal inoculation. The organism grows on the surface of 5 per cent. crude oil and 5 per cent. glycerine as a thick uniform greasy pellicle. Microscopically it alters considerably in shape and form; it begins to *branch* (Fig. 1). Branching is also seen in the refined oil (5 per cent.), but not to so great an extent. The stage of growth here represented shows the branching forms here and there in a field, the remainder of the field being occupied by rod segments. The rod segments also are more filamentous and irregular, the latter from the breaking-up of their substance by the formation of granules and in some of them by the presence of little offshoots, the beginnings or the stumps of their ramifications. At the same time they stain with greater difficulty. The staining portions of the segments do not as a rule stain with their usual vividness. The slide requires to be well heated for eight or more minutes. Branching appears in most cases to occur where there is a large "granule" present. In others small lateral offshoots seem to arise from the segments without any granule being visible, possibly false branching. Granules form in the segments as they grow, and they in their turn give off other segments. Further evidence that these "granules" are essentially bodies whose function is to germinate can, I think, be seen in animal inoculation. Fig. 2 represents oil bacilli after passage through a guinea-pig. The culture was a two-months-old growth on 5 per cent. refined oil and 6 per cent. glycerine. The growth, not emulsifying with watery fluids, was ground up with olive oil in the proportion of two loopfuls of growth to a cubic centimetre of olive oil and then injected intraperitoneally. The animal died 22 days later. The necropsy showed the liver, spleen, omenta, and glands nearly solid with tubercles. A portion of the tuberculous material was then placed in a mortar, and films were made of the expressed juice. Microscopically, there are a large number of "bacilli" present, some 20–30 in a field, nearly all of which are as those depicted, the remainder being of the ordinary rod form. It will be noted that the "granule" or "spore-body" is generally larger than the culture "granule"; it is also sharply defined and intensely stained, and has attached to it the bacillary portion of the organism. It is also to be noted (Fig. 2) that there are forms present in which two "spore-bodies" are fused together, not in juxtaposition, with their bacillary portions issuing out at opposite poles. They are not so commonly met with as the single form. With the above characteristics it is difficult to regard these bodies in any way as degenerative. The bacillary, or rod portion, of the organism varies in length and in staining power. The long forms[5] may have more than one spore-body in their length. In their manner of staining they are to be found in all stages, from not staining at all with carbol-fuchsin to being firmly acid-alcohol-fast.

---

[1] Cultivation of the Tubercle Bacillus: Change in Form by Growth on Sperm Oil and Glycerine-Egg Medium, THE LANCET, Sept. 19th, 1914, p. 739.

[2] These changes are, of course, not peculiar to the oil media. One often sees similar "abnormal" forms in old cultures on other media. For instance, I have a culture of human bacilli on Dorset's medium. It had grown very well, but had been allowed to become dry. When examined at a growth of five months the rods had grown for the most part longer; they showed all stages from not taking the stain at all to well-stained segments, and there were an enormous number of granules present, especially noticed after being decolourised (acid-alcohol). A slide fixed with a saturated solution of corrosive sublimate is not different from one fixed by passing through flame.

[3] At the best the term, in its reference, is not a good one.

[4] 5 per cent. is not the limit. A strain of bovine is growing well on 8 per cent. crude oil and 5 per cent. glycerine.

Besides the above, one meets forms identical with those of the original culture apparently unchanged some two to three weeks after a peritoneal injection. In general, from one's present experience, it appears (see above) that the longer the animal lives the more the above forms tend to assume or become the ordinary rod form; they have been obtained in pure culture from the animal tissues.

Members of the streptothrix group are known to acquire acid-fast characters with age.

I wish to express my sincerest thanks to Mr. A. R. Smith, M.Sc. Lond., chemical expert to Messrs. Joseph Watson and Sons, soap manufacturers, Leeds, for the suggestion of the use of a liquid wax. Sperm oil, being a liquid wax, was accordingly chosen. In the earlier part of this work solid waxes were added to agar—e.g., beeswax, gondang, pisang, carnauba, Chinese wax, some with glycerine and some without. As might be expected, the waxes did not mix[6] with the agar. In spite of this growth occurred slightly on bees' and Chinese wax, an insect wax. I also desire to acknowledge my indebtedness to Professor A. E. Boycott, for giving me permission, and all facilities, for performing the animal experiments of this work in his laboratory, as well as to Mr. A. G. R. Foulerton, of University College, London, and Dr. J. C. G. Ledingham, of the Lister Institute, for kindly giving me cultures of streptothrices and tubercle bacilli.

The Joint Hospitals Pathological Department, Manchester.

PNEUMOCOCCAL INFECTIONS TREATED WITH AUTOGENOUS VACCINES.

By NATHAN RAW, M.D. Durh., M.R.C.P. Lond.,
LIEUTENANT-COLONEL, R.A.M.C. (T.); SENIOR PHYSICIAN, LIVERPOOL MERCHANTS' WAR HOSPITAL.

The following is a brief note of three cases of very virulent pneumococcal blood stream infection, in which, in my opinion, the patients would certainly have died but for the employment of autogenous vaccines.

The great mortality from pneumonia and the disappointing results in a great many cases from ordinary medicinal treatment compel us, as a profession, to employ every means in our power to minimise this heavy fatality, and I am convinced that in a great many cases (I candidly admit, not in all) we have in vaccine a valuable remedy which will, if given in the early stages of the infection, turn the scale in favour of recovery.

During the last five years I have treated in hospital and elsewhere 310 cases of pneumonia with vaccine with 42 deaths, or a mortality of about 13 per cent. In many of these cases vaccine was administered on the second or third day of the disease, and was given every four hours or at longer intervals, according to the severity of the case, and although the results have not always come up to our hopes and expectations, yet I have never once observed any unfavourable symptom follow the use of vaccine in whatever dose it has been administered.

The much debated question as to whether or not a vaccine should be given in the course of an acute infective disease must, in my opinion, be answered in the affirmative, and during a recent visit to France I was much interested to find that acute cases of typhoid fever with high temperature were being treated with antityphoid vaccine with excellent results, and I feel sure that in the near future this form of treatment will become more generally used by physicians.

A vaccine to be potent ought to be autogenous—that is, it should be prepared from the sputum or blood of the patient—and if this can be prepared quickly it can often be used with good effect.

I will briefly mention three very severe pneumococcal infections which were treated as a last resource by autogenous vaccines, and, I am glad to say, successfully.

Case 1.—A young man, aged 30, was seen in consultation with Dr. Williams. He was suddenly attacked with acute lobar pneumonia of the right base, which rapidly spread upwards, and in a couple of days the other lung was involved. The toxæmia was severe, the temperature reached 105° F., and the pulse-rate was 160. In addition to general treatment he had several injections of stock pneumococcus vaccine and after a great struggle up to the ninth day he had a favourable crisis. Six days after the crisis he developed a large fluctuating swelling in the right lumbar region, which on aspiration was found to contain thin creamy pus full of pneumococci. The swelling was freely incised and drained and was followed by similar abscesses in the neck, the left elbow, and, finally, an enormous swelling over the left hip. This was opened and drained by Mr. D. Douglas-Crawford. About this time the patient commenced to expectorate a large quantity of similar pus, and it was evident that he had an abscess on the right lung. I inoculated a mouse at the Liverpool University, which died in 24 hours from septicæmia. From the heart's blood a pure culture of pneumococcus was readily obtained and a vaccine was prepared. In all Dr. Williams gave him 16 injections of this autogenous vaccine, commencing with 50 millions and rising to 100 millions at a dose. The patient became alarmingly thin and wasted, but after several months of suffering, during which at many times he was not expected to recover, he slowly rallied and is now quite well, with the exception of a little restricted movement of his hip-joint. In this case the improvement only showed itself after the autogenous vaccine was commenced, the patient's condition not being influenced one way or the other by the homologous vaccine.

Case 2.—A female, aged 25, was seized on the onset of her confinement with a very severe rigor and pain in her right chest. The child was born in a few hours, but the mother rapidly became delirious, with a temperature of 105·2° F. and a pulse-rate of 144. Pneumonia supervened in the right lung, with complete consolidation of all lobes. The patient was in a critical state for eight days, and Dr. James Marsh, of Atherton, with whom I saw the case, remained in the house for over two weeks. Several injections of homologous vaccine were given to supplement the ordinary restorative treatment, and apparently with good effect. On the twelfth day she developed a painful swelling in the left shoulder-joint, extending down the arm and pointing over the bicipital groove. This was opened and drained, and from the pus, which was pneumococcal in appearance, I inoculated two mice at the

---

[5] Some of these rods may be undergoing degenerative processes.

[6] The difficulty was overcome by adding a little neutral soap, but the bacilli did not grow.

University, and from the blood obtained a vigorous culture of pneumococcus. A vaccine from this culture was prepared and given in doses of 100 millions daily, as the case was desperate. In two days another large swelling appeared over the left hip, which tracked down the thigh under the fascia lata; this was also opened and drained. The pus contained enormous numbers of pneumococci. The patient had in all 14 injections of autogenous vaccine, and finally she made a good recovery. There is still some stiffness with adhesions in the left shoulder, but otherwise she bears no trace of her virulent infection.

CASE 3.—A girl, aged 16, was admitted to the hospital suffering from acute lobar pneumonia with great pain and distension of the abdomen. The pneumonia ran a very acute but short course and the crisis occurred on the fifth day. The abdomen being still very painful and tender to pressure it was thought necessary to explore it. On opening it in the middle line a large quantity of creamy pus escaped, which under the microscope was found to swarm with diplococci and well-marked capsules. Two mice were inoculated and a vaccine was prepared. The abdomen was drained for ten days and after six injections of autogenous vaccine the discharge ceased and the patient made a slow but complete recovery. In the course of her illness she developed puffy swellings over both elbows and the right shoulder. These swellings gave every appearance of suppuration, but after constant fomentation with boracic lotion they slowly subsided and entirely disappeared.

I am convinced that we have in pneumococcus vaccine a valuable aid in the treatment of pneumonia, and although not a specific remedy it ought always to be used in those cases of a virulent type which threaten the life of the patient.

Liverpool.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

DYSPEPSIA OR ULCER?

BY I. B. MUIRHEAD, M.D., C.M. GLASG.

THE following case illustrates a point in the diagnosis of gastric ulcer hitherto little noticed. Whilst emphasising the differences of opinion which still divide the profession with regard to the question of operation, it suggests that localised pain, associated with diminishing weight, may come in many cases to be looked upon as a sufficient indication for surgical interference.

The patient, a woman aged 40, was seen on Sept. 21st, 1914. Three months previously she began to suffer from pain after eating, vomiting, constipation, and failure of strength. Her weight had fallen from 9 st. to 6 st. Vomited matters were usually grey or whitish in colour, occasionally darkish brown; contained no blood. No blood passed from bowel. Inability to procure sufficient food might have had a share in causing the illness, but this was denied very strenuously. The extreme emaciation, languid look, feebleness, and obvious anæmia were striking. In the abdomen, beyond tenderness on palpation, nothing abnormal was found. The position of the pain centre was, however, rather out of the common. It was definitely fixed at the junction of the upper and middle thirds of the line separating the left lumbar and umbilical regions. Here pain after eating was chiefly felt, and this was nearly always the situation of the pain, which led up to the attacks of vomiting. It may be stated that while later pain was frequently complained of elsewhere, the position mentioned, somewhat above and to the left of the umbilicus, was always recognised by the patient as the seat of her chief and permanent pain. No enlargement of the spleen or lymphatic glands; urine normal.

From Sept. 21st to Nov. 4th treatment relieved both pain and vomiting up to a certain point, but the decline of strength and weight showed no improvement. It therefore became obvious that, if surgical treatment was to be given a chance, the time had arrived. She accordingly went to hospital, with a certificate that, in the opinion of her medical attendant, she was suffering from an organic gastro-intestinal trouble. Though the certificate did not mention operation, the patient understood my views and the object of her visit. At the hospital three separate examinations, each lasting about a quarter of an hour, were conducted by different members of the staff, whose unanimous conclusion was that "they could find nothing beyond a history of dyspepsia and constipation."

As already stated, the patient denied that she had ever vomited blood, and down to Nov. 4th repeated examinations failed to discover a single unequivocal hæmatemesis. Almost immediately on returning from hospital she began to vomit blood, and continued to do so in considerable though diminishing quantities for about a week with the usual debilitating effects, accentuated by her already reduced state. From Nov. 10th to 15th, and again on the 21st, dark tarry motions were passed. After the 22nd no blood appeared externally, she vomited seldom, had comparatively little pain, and took nourishment fairly well. Apart from a slight tonsillitis from Nov. 27th to Dec. 3rd the lull in the acute symptoms continued till the morning of Dec. 11th, when rather severe abdominal pain was again complained of. At 11 A.M. on that day her appearance suggested a recurrence of bleeding, her pulse was quick and feeble, and her breathing laboured. She died the same afternoon. A necropsy was refused. In conclusion, I should like to make mention of the services rendered by the King's nurses.

Stoke Newington, N.

NOTE ON THE USE OF ANTISTREPTOCOCCIC SERUM IN ACUTE BRONCHITIS.

BY J. G. HAYES, L.R.C.S., L.R.C.P. IREL.

I DO not know if antistreptococcic serum has been widely used in the treatment of acute bronchitis, but a few remarks on my own personal experience of its use may not be out of place. First of all, I believe I am right in saying that in the majority of cases of bronchitis, and particularly the more severe forms, some strain of streptococcus plays an important rôle; anyway, in cases where I have had the sputum examined streptococci have nearly always been found. The following are examples in which I have used the serum:—

CASE 1.—The patient was a woman, about 30 years of age, the subject year after year for some considerable time of recurrent attacks of very acute bronchitis associated with high temperature and great prostration, necessitating confinement to bed for nearly two months at a time. On the occasion of an attack in the beginning of 1913, which was a particularly severe one, autogenous vaccines were used, and though the doses were below the average they were followed by such dangerous reactions that they had to be discontinued after the fourth injection. In 1914 the patient developed symptoms that suggested a recurrence.

There were rigor, pains in the back, rise of temperature, cough, and general malaise; also faint râles quickly became evident over both lungs. I determined to give a polyvalent antistreptococcic serum with as little delay as possible, so that evening, at 9 o'clock, I gave 3000 units of antistreptococcic serum, the temperature being then 102·4° F. The patient had a comfortable night and on the following morning the temperature was 99·6°. It rose towards evening again to 101·4°, so I repeated the injection of serum, and after another comfortable night the morning temperature read 98·8°, above which it made no further rise. Some ten days later, when the patient was up and about, symptoms recurred, but the temperature only reached 100·8°. However, I again administered serum precisely as before, with the result that the following day the temperature was normal, and has remained so ever since.

CASE 2.—The patient, a girl aged 19 years, developed acute laryngitis followed by symptoms of general bronchitis. When I saw her the temperature was 103·2° F. Polyvalent antistreptococcic serum, 3000 units, was administered. On the following morning the temperature was 101°; no rigors; cough soft; expectoration easy. The temperature that evening was 99·8°, and from this time on there was a general abatement of symptoms with rapid recovery.

CASE 3.—The patient was a man, aged about 63 years, the subject of chronic bronchitis with frequent acute exacerbations during the winter months. I saw him for the first time in the early stages of one of these acute attacks. I gave him the serum as in the previous cases, which was followed by an improvement that was progressive and maintained, so that no repetition of the treatment was necessary.

From these results I formed the following conclusions: 1. That the streptococcus was the main cause of the toxæmia in most case of acute bronchitis. 2. That, giving an antistreptococcic serum in the early stages will increase the blood resistance against the micro-organism that is likely to cause the most serious trouble. 3. That the serum may be given and repeated without the fear of such dangerous reactions as I, at any rate, have experienced with vaccines. 4. Serum has the great advantage that it can be got at once, where a vaccine, which if it is to be any good, must be autogenous, and cannot be secured for some days.

It would be interesting to have the opinions of others on this subject, for certain it is that, provided proper aseptic precautions are carried out, the early treatment by serum injection is associated with very little risk, and will help to combat a very common and dangerous enemy which is ever waiting to find an entrance to the human body. The treatment applied to other acute diseases may give similar results, but the effect on these cases impressed me considerably.

St. James's-place, S.W.

EDINBURGH SICK CHILDREN'S HOSPITAL.—The annual meeting was held in the board-room of the hospital on March 17th. Mr. Charles I. G. Paterson, vice-chairman of directors, presiding, referred to the absence at the front on military service of their chairman, Colonel James Clark. He took the opportunity of publicly thanking Colonel and Mrs. Clark for all they had done for the hospital. Fifty years ago, he said, they had only 20 beds; now they had 120, and 2166 children had passed through the wards in the year. The out-patient departments showed the equivalent of 27,000 visits. The year's expenditure was about £9600, but still there was a deficit of £3800 which had to be met out of the legacies. Dr. A. H. Freeland Barbour, President of the Royal College of Physicians of Edinburgh, moved a resolution commending the Children's Hospital to the liberality of the public. The care given to children reduced the mortality of the city and might preserve to the country a Jellicoe or a Kitchener.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION OF DERMATOLOGY.

Exhibition of Cases and Specimens.

A MEETING of this section was held on March 18th, Dr. J. J. PRINGLE, the President, being in the chair.

Dr. J. A. NIXON showed the Parasite "Pediculoides Ventriculosus" responsible for the disease known as "cotton-seed dermatitis," an epidemic of which occurred among dock labourers in Bristol in January, 1915, the parasite probably being the same as that causing "barley itch."—Dr. A. WHITFIELD demonstrated the Acarus obtained from a specimen of Copra which was responsible for the disease known as "copra itch"; the lesions were almost identical with those described by Dr. Nixon and yielded readily to treatment by sulphur ointment. It was surprising that although the disease was well known to practitioners in the East End of London it was not generally recognised in the hospitals.—Dr. J. M. H. MACLEOD had seen one case of copra itch and one of cotton-seed dermatitis. He had come to the conclusion that in the latter condition the acarus was a parasite of a caterpillar found in great abundance in the cotton seeds.—Dr. GRAHAM LITTLE and Dr. G. PERNET discussed the cases.

Dr. J. H. STOWERS brought up two brothers with Alopecia due to over-dosage of X rays in the treatment of ringworm. —Dr. DUDLEY CORBETT, Dr. KNOWSLEY SIBLEY, and Dr. PERNET discussed the prognosis.

Dr. PERNET showed a case of Iodide Eruption with much pigmentation in a man suffering from syphilis who had treated himself with a familiar "blood mixture."—The PRESIDENT, Dr. WHITFIELD, Dr. A. EDDOWES, and Dr. PARKES WEBER discussed the case.

Dr. PERNET also showed a typical case of Non-ulcerating Erythema Induratum in a girl aged 15.—The PRESIDENT and Dr. GRAHAM LITTLE made observations on the case.

Dr. SIBLEY brought forward a case of Nodular Lupus Vulgaris complicated with Lymphangitis in a girl aged 18, in which the microscopic appearances were unusual and the von Pirquet reaction negative.—Dr. WHITFIELD considered the sections to be typical of lupus vulgaris. He thought that the disease was likely to be aggravated by the streptococcal lymphangitis.—The case was further commented on by Dr. H. G. ADAMSON, Dr. S. E. DORE, Mr. J. E. R. MACDONAGH, and Dr. DOUGLAS HEATH.

Dr. DORE and Dr. KINNIER WILSON showed a case of probable early Anæsthetic Leprosy in which there was dissociation of sensation in the lower extremities with thickening of the skin over the knuckles, blisters between the toes, and dystrophy of several nails both of hands and feet.—Dr. WHITFIELD suggested the Wassermann test in addition to a tuberculin injection.—Dr. PARKES WEBER and Dr. PERNET favoured the diagnosis of leprosy.

Dr. ADAMSON showed a case of large Circinate Lichen Scrofulosorum in an adult.—The PRESIDENT remarked on the rarity of this condition in adults as compared with its frequency in children.

Dr. ADAMSON also showed a case of Macular Atrophy and accentuated the toxæmic origin of the condition, which was often due to syphilis or tuberculosis.

Mr. H. C. SAMUEL exhibited a Linear Nævus on the thorax, neck, axilla, and forearm of the left side. The condition had not manifested itself till 16 years of age.—Treatment by means of carbon dioxide snow was discussed by Dr. GRAHAM LITTLE and Dr. ADAMSON.

Dr. PARKES WEBER demonstrated a case of Generalised Atrophic Sclerodermia with Sclerodactylia in a middle-aged woman. He made special reference to the absence of pulsation in the dorsalis pedis arteries, an observation which was confirmed by Dr. STOWERS.

Dr. GRAHAM LITTLE brought forward a boy with Simultaneous Herpes Zoster of the third and eighth left dorsal segments, the intervening areas being free from lesions; he considered the case unique.—The PRESIDENT, Dr. A. M. H. GRAY, Mr. SAMUEL, Dr. ADAMSON, and Dr. HEATH spoke on the subject.

Dr. GRAHAM LITTLE further showed (1) a case of Epithelioma of the thigh in a woman, aged 63, resulting from an injury to a congenital pigmentary patch; and (2) a case of Dermatitis Herpetiformis in a boy, chiefly affecting the neck, chest, and groins.—The PRESIDENT commented on the difficulty of differentiating between Duhring's disease and pemphigus, and Dr. ADAMSON concurred.—Dr. HEATH agreed with the exhibitor's diagnosis, and advocated the exhibition of arsenic.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF MEDICINE.

Exhibition of Case of Lupus Vulgaris.—X Ray Treatment of Ringworm.—Prophylactic Inoculation against Tuberculosis.

A MEETING of this section was held on March 5th, Dr. W. G. SMITH, President of the Academy, being in the chair.

Dr. C. M. O'BRIEN showed a boy, aged 13, who was suffering from a very pronounced form of Lupus Non-exedens for the last nine years. Although widespread, the face and mucous membrane were practically free. Since admission on Oct. 8th, 1914, the boy had gained 11 lb. For almost three years he had received at the London Hospital one hour's exposure of Finsen light on five days of the week. Since Oct. 8th, 1914, he had had three sittings per week of 70 minutes each. The most that could be claimed was that it stopped the spread. Dr. J. Griffiths, of Cambridge, had inoculated a guinea-pig from the lupus tissue with positive results.

Dr. E. J. M. WATSON read a paper on X Ray Treatment of Ringworm.—Dr. SMITH said the whole point of X ray treatment was that this method had reduced to weeks a period of treatment which was formerly measured in months. The only change in X ray treatment in recent years seemed to be the substitution of frequent exposure to small doses for larger doses given at longer intervals. To epilate a child's head was a troublesome process, and he suggested that X ray treatment was forceps treatment abbreviated. He maintained that no case of ringworm should be certified as safe so long as one diseased hair could be found.—Dr. W. G. HARVEY could support Dr. Watson's statement that occasionally cures occurred without epilation being complete. The diseased hairs were more freely epilated than the healthy. He had usually employed an antiseptic ointment, believing its effect to be mechanical.—Dr. O'BRIEN said that notwithstanding diversity of opinion as to the effect of X ray treatment on ringworm, the statistics of Paris should leave no doubt as to the efficacy of the procedure. Sabouraud held that at the end of 1906, after three years' work, the municipality of Paris had gained financially 2½ millions of francs by the adoption of X ray treatment. He had made it a *sine quâ non* before treating a child under the age of 3 to get the consent of the parents in writing, as it had been suggested in some cases treated in London that the exposure to X rays had some effect on the brain of a child.—Dr. M. R. J. HAYES, in regard to permanent alopecia as a result of the treatment, suggested scrupulous accuracy in the measuring of the dose and caution in the use of old tubes in the treatment of ringworm, as one could not be sure of their vagaries. Tubes which had been used for many hours in a period of months would give off rays greater than one would expect. He had used cataphoresis with copper sulphate ions, but this was somewhat troublesome and was more painful.—Dr. WATSON, replying, said his practice was to expose each area with the dose of one Sabouraud for a quarter of an hour. If one's tube was new and working properly he did not think there was any danger of baldness even in very susceptible cases.

Dr. W. M. CROFTON read a paper on Prophylactic Inoculation against Tuberculosis, and said that practically everyone who attained to adult years got infected with tuberculosis. Two objects presented themselves: (1) to prevent the microbe obtaining access to the patient; (2) to make the patient's tissue unsuitable for the development of the microbe. While it appeared impossible to prevent the microbe gaining access, only a proportion of those infected developed the disease to a serious extent. The recovery of the majority was due to a normal resistance; therefore the problem would be solved if the resistance of the minority could be made and kept normal. Low resistance was due to (1) bad hygienic surroundings; (2) lowering of resistance by other microbes; and (3) inhibition. A normal resistance might be overcome by a virulent infection. General sanitary measures, while they kept down morbidity and mortality to a certain level, would not entirely prevent disease. The only method was to render the soil unsuitable by prophylactic inoculation. The probability of the success of this measure and the method of carrying it out were discussed. T.R. was used dissolved in liquid paraffin containing 2 per cent. benzoyl chloride. The doses were given at intervals of a week, increasing ten times each administration. They began at one-millionth of a milligramme and rose to one-thousandth for infants. Ten times these doses might be given to older children, and for adults an extra dose of one-tenth milligramme might be given. The test of success would be the reduction of case incidence and of mortality. The experiment was innocuous, cheap, and easily carried out. A beginning might be made in families in which tuberculosis had occurred.—Dr. T. G. MOORHEAD said that he had come to the conclusion that tuberculin as a prophylactic remedy against tuberculosis was not of much value. As one looked around, two types of infective disease were recognised. Of one, small-pox was the type, and of the other tuberculosis. In tuberculosis it would seem that a sufficient amount of antitoxin was not produced to prevent a patient from getting a second attack. A survey of such remedies showed that certain of them had been permanently accepted as useful—e.g., vaccination for small-pox and 606 for syphilis; but of tuberculin, although it had been before the profession now for over 20 years, the value had not become admitted, and at the Congress of Medicine much doubt was expressed as to its utility.—Professor B. J. COLLINGWOOD asked if it was not possible that the liability to tuberculosis which exists in certain individuals is due to the fact that they do not possess the power to produce antibodies to prevent tuberculosis?—Dr. SMITH and Dr. LAW also spoke.

ÆSCULAPIAN SOCIETY.—A meeting of the above society was held in the Metropolitan Hospital on March 19th, Dr. David Ross, a Past-President, being in the chair.—The resident staff showed some interesting cases and skiagrams.—Mr. W. S. Soden showed: 1. A man with a large mass in the abdomen, found on operation to be fixed to the abdominal wall. Gumma was suggested. 2. A man, aged 50, with rapidly growing Epithelioma of the Soft Palate on the left side, treated by diathermic cautery with excellent results. 3. An anæmic man with Chronic Laryngitis of doubtful origin, syphilitic or tuberculous. Wassermann reaction negative even after provocative dose of neosalvarsan. No tubercle bacilli were found. 4. A man, aged 26, with Comminuted Fracture of the Right Clavicle. 5. X Rays of Shrapnel Wounds showing metal remaining after healing of wounds.—Mr. C. K. Sylvester showed: 1. Skiagram of a Bullet in the Muscles of the Back. 2. Case of Cerebro-spinal Meningitis, no loss of abdominal reflexes, and persistent Kernig's sign. Diplococcus found only on third examination. Three grains of soamin were administered on March 4th and two grains on March 10th, followed by fall of temperature for two or three days. An unexplained rise of temperature proved to be the onset of measles. 3. Spasm of Cardiac End of Œsophagus. History of vomiting for two years. A bismuth meal revealed great dilatation of the œsophagus ending in a cone-shaped shadow. No evidence of new growth. Jejunostomy suggested, and later when the condition improves gastrostomy.—Mr. Mawer showed: 1. A boy, aged 14½ years, with swelling under the mandible on the left side, noticed by him since Dec. 14th. After discussion a cystic hygroma was diagnosed. 2. A small female child, aged 4 weeks, with a cystic swelling of the left buttock, which was agreed to be an anococcygeal cyst. Treatment was deferred until the child had acquired control of her anal sphincter.—Mr. Dive showed: 1. A woman, aged 54, with Adiposis Dolorosa. The treatment consisted of the administration of thyroid and pituitary extracts. 2. A child, aged 7 months, with painless bony swelling of two weeks' duration of the proximal phalanx of the right fourth finger. Diagnosis: T.B. dactylitis, confirmed by X rays. 3. A child, 6 weeks old, suddenly noticed to have a swelling of the right elbow; false paralysis of that arm. Diagnosis of epiphysitis.

Reviews and Notices of Books.

Feeble-mindedness : Its Causes and Consequences. By HENRY HERBERT GODDARD, Ph.D., Director of the Research Laboratory of the Training School of Vineland, New Jersey, for Feeble-minded Girls and Boys. New York: The Macmillan Company. 1914. Pp. 599. Price 17*s*.

THE main object of this book, as stated in the first chapter, is to consider the problems of crime, pauperism, intemperance, and the social evil from a new standpoint; and the new hypothesis with which the author starts may be shortly summed up as follows: There are all grades of responsibility—or all grades of intelligence—from zero to the highest; that responsibility varies according to the intelligence; that intelligence is a relative matter, and certain people may therefore be responsible in some environments while they would be irresponsible in others; and that in order to grade responsibility with a view to social work and treatment the intelligence must be measured and an attempt made to draw the line between normal intelligence and defect. The author proceeds to state that persons "below the line of normal intelligence" have been at different periods called by different names; being originally styled "idiots," later "imbeciles," and, still later, "feeble-minded"; and that now, by common consent, the custom has grown up of applying the term "feeble-minded" to the highest grade of defectives only, confining the two other terms, "imbecile" and "idiot," to the middle and lowest grades respectively. This, he correctly says, is now the common classification in England, and he also mentions that, as a general term for all groups, the word "aments" is sometimes used. But in America the word "feeble-minded" has been for long widely used both as the generic term for all and for the highest grade alone; and the author informs us that since what is known as the "Binet measuring scale of intelligence" and the grading of children by their "mental age" have been adopted in America, the term "moron" has been substituted for "feeble-minded" as the designation of the highest grade. It is claimed that the study of "morons" in American institutions for the feeble-minded has resulted in the drawing of a line which marks the degree of intelligence to which these people cannot reach, and are consequently incapable of functioning properly in a highly organised society.

Following on these preliminary statements, and in relation to them, the social problems of alcoholism, crime, prostitution, and pauperism are successively considered.

For the rest, this book consists chiefly of a detailed series of 327 unselected cases, not of "morons" only but of all ages and grades of defect; and it is said that the theories presented and the conclusions arrived at have been merely those that were suggested by the data themselves. Among the chief conclusions that have been forced on the author by the figures is that normal intelligence is a "unit character," transmitted in true Mendelian fashion.

We have no space to deal at length with the elaborate records of cases which occupy by far the largest portion of this book. Whether or no the conclusions appeal to thoughtful (or, according to the peculiar orthography which pervades this work, *thotful*) readers, these records will be of interest to the clinical student of mental defect. But the classification of cases into several groups, such as hereditary, probably hereditary, neuropathic, accidental, and so forth, seems to us to be very superficial; to involve confused notions regarding the meaning of heredity; and to consist, in a great degree, of mere opinions. To give one instance, a certain boy classed as a high grade (moron) was the only living child of a mother who had had eight miscarriages or stillbirths. The mother was a "normal," of a normal family; the father was also normal, "but evidently a carrier of defect, since his mother was feeble-minded. He was alcoholic, and went with a fast set, which undoubtedly accounts for the miscarriages. To confirm our theory that the father must have been a carrier of 'feeble-mindedness,' we have only to look at an older brother who is feeble-minded, and married a feeble-minded woman. ...... There is no doubt that this boy has inherited the defect thru his paternal grandmother."

One of the most glaring faults in this book is the elementary mistake of regarding "intelligence" as synonymous with "mind," an error which marked also the essay of Professor Karl Pearson on this subject, which was reviewed in THE LANCET of Jan. 2nd. Indeed, Professor Pearson appears to us to have had in view the work now under consideration when writing his paper, in that he not only pointed out that there are other factors, such as the "moral" factor (which he does not consider "mental"), in the complex commonly known as "feeble-mindedness," but also set forth his own refutation of the teaching that mental defect is to be regarded as a Mendelian trait due to the absence of the "unit character" of normal-mindedness from the germ-plasm. We agree fully with Professor Pearson in his demolition of this theory of a "unit character" in relation to feeble-mindedness, and thus may pass over this doctrine, which is emphasised so strongly in this book, without further notice.

The diagnosis of "feeble-mindedness," or "moronism," is not a matter concerning the intelligence only. It is a matter of *mental defect* (in the proper sense of that word), as evidenced chiefly by careful observation of conduct and by study of the history of each case, leading to an inference of the incapacity of the subjects to adjust themselves effectively to their social surroundings. We believe that no definite hard-and-fast standard of intelligence alone, such as that adopted by the author, for facilitating clinical work, nor, again, any prescribed method of "standardising judgments as to the grade of social inefficiency which shall involve segregation," as hoped for, but not indicated, by Professor Pearson, is to be reached or sought for. On the other hand, we hold that, in spite of inevitable differences of opinion regarding some cases, a careful history and prolonged observation of most alleged instances of feeble-mindedness will enable most students of mental defect to come to a right and practically useful conclusion. We agree to a certain limited extent with the author's views as to some causal relation of feeble-mindedness to crime, alcoholism, prostitution, and pauperism, but believe that the far-reaching conclusions arrived at by him are not borne out by facts, and would be very misleading if regarded as duly established.

We have not entered here into the question of the "heredity" of feeble-mindedness because there is a general agreement, whatever views may be held as to the nature and mode of heredity, that there is a vastly greater probability of offspring with marked mental defect being born of forebears with a similar defect than of those not so characterised. There is, of course, much evidence to this effect in the interesting cases reported in the book before us; but we find nothing that can be regarded as of fresh scientific or practical import.

The Anatomy of the Human Skeleton.

By J. ERNEST FRAZER, F.R.C.S. Eng., Lecturer on Anatomy in the Medical School of St. Mary's Hospital; formerly Lecturer at King's College, London; Senior Demonstrator at the Medical School of St. George's Hospital; and Examiner in Anatomy for the Conjoint Board of the Royal Colleges of Physicians and Surgeons. With 219 illustrations, many of which are coloured. London: J. and A. Churchill. 1914. Pp. 274. Price 21*s*. net.

IT is but rarely that a reviewer experiences the real pleasure afforded by the reading of a book on human anatomy which may truly be termed new—new both in its illustrations and in its text. But such a book is that produced by Professor Frazer, which possesses the added charm that in the very manner of treating the subject the author has struck out new lines for himself. Among the flood of new editions and reprints which it is our lot to wade through, this book comes with its novelty as a particularly refreshing thing; and it must be remembered that if this sense of relief should unconsciously colour the impressions of the reviewer, it is likely also to have its influence upon the student, perhaps wearied by the monotony of his old companions. This is a virtue difficult to over-estimate.

Professor Frazer has more nearly than any recent writer "made the dry bones live" for the student of anatomy, if we may be pardoned the old quotation. He has placed the bones before the student as functioning parts of a living body; a mass of mere description of surfaces and borders is avoided, and the bone is studied in all its complex relations to the surrounding structures. It is safe to say that the knowledge gained by the student from following such a course is far more real, and far more likely to be useful than that gained by any method such as the one (alas, ascribed originally to the great Vesalius!) of carrying dried bones at all times in the pocket. We think, perhaps, that the book does not end quite so well as it begins; that the treatment of the skull is not carried out quite so fully as is that of the rest of the skeleton; but this must not be taken as saying that the work here is not done in an excellent and sensible manner.

The illustrations are the work of the author and they are bold and striking, and the text is clear and ample. Two things will, we think, be criticised by a lecturer on anatomy, who is regarding the work as the most recent text-book of the science of osteology, rather than as a work from which the medical student may learn of the human skeleton. In the first place, few authorities are named and practically no references are given to the literature; in the second, the old terminology has been retained. It is perfectly obvious that this is deliberate on Professor Frazer's part, and we commend his attitude; for if we regard the work as a handbook for medical students, it is not difficult to see that these very features are in reality positive virtues in such a book. Professor Frazer is to be congratulated upon the production of this volume, for in it the medical student has been provided with a book on bones which he can read with interest, which will put him on the right lines for finding out more for himself, and will give him knowledge that will serve him long after his student days.

The whole "get up" of the book is good—we have here, in short, one of the best additions to the student's library made of recent years.

The Practice of Surgery.

By JAMES GREGORY MUMFORD, M.D., Lecturer on Surgery in Harvard University, &c. Second edition, thoroughly revised. With 683 illustrations. London and Philadelphia: W. B. Saunders Company. 1914. Pp. 1032. Price 30*s*. net.

THE present edition of this book has been fully revised so as to record the progress and changes that surgery has undergone in the four years since it first appeared, and we wish to reiterate the very favourable opinion that we expressed of the book at that time. The reader will be impressed with the tone of the author, and will recognise that he writes from a wide experience and with a calm judgment capable of estimating correctly the new facts, theories, and methods which are always being brought forward, though there may be some things in the book with which he can hardly agree. The author states in his preface that he has read 70 reviews of his book and that his reviewers do not always agree with him, but adds that neither do they always agree with one another, a comment which shows the book to be a really thoughtful work maintaining a high standard.

The illustrations are all that can be desired. In our former review we referred to the frontispiece which represents the changes that have taken place in surgery, one picture showing the first public demonstration of ether anæsthesia in the Massachusetts General Hospital on Oct. 16th, 1846, and the other showing an operation in the same hospital in May, 1908. The difference is very striking, but some surgeons of to-day would say that even the latter picture does not show the practice of 1915.

Carcinoma of the Thyroid in Salmonoid Fishes.

By H. R. GAYLORD and M. C. MARSH. With 55 plates. Buffalo, N.Y.: State Institute for the Study of Malignant Disease. 1914. Pp. 524.

THIS large quarto monograph falls naturally into two parts: one dealing with the histology and morbid anatomy of thyroid enlargement, and the other devoted to a discussion of the conditions associated with varying frequency of the disease and experimental variations of these conditions. The plates refer almost entirely to the first part, and give a very complete picture of the structure of the conditions from the earliest hyperplasias to the most advanced growths. Being mostly prepared from microphotographs they show the limitations of this method of illustrating histological work, the most successful photographs being those taken with very low powers. While these are all admirable, the same cannot be said of the higher magnifications. This indistinctness is particularly unfortunate in the case regarded as a visceral metastasis from a thyroid tumour. The importance assigned to this case by the authors makes it all the more regrettable that only presumptive evidence could be adduced of the coexistence of a thyroid tumour in the fish in question. The conclusion is drawn, from the completeness of the series of transitional forms between the slightest degrees of hypertrophy and the large atypical destructive growths, that "endemic goiter and carcinoma of the thyroid in the Salmonidæ are the same disease."

From their study of the conditions under which the disease appears in fish hatcheries, and from their experiments, the authors conclude that this disease is due to a water-borne virus, and that the liability of fish to it is enhanced by artificial proteid feeding, overcrowding, and other factors. In addition to the beneficial effect of iodine already noted by Marine, mercury and arsenic are also stated to influence the condition in the same way. The numbering of the pages seems to have been altered in the press, as the authors' references to their own observations are all incorrect. This adds a needless difficulty to the task of following their arguments.

Water Supplies: Their Purification, Filtration, and Sterilisation.

By SAMUEL RIDEAL, D.Sc. Lond., and ERIC K. RIDEAL, B.A. Cantab., Ph.D. Bonn. With numerous illustrations and tables. London: Crosby Lockwood and Son. 1914. Pp. 274. Price 7*s.* 6*d.* net.

THE subject of water-supplies is approached in this book mainly from the standpoint of modern methods of purification, and as the advances made in this direction have been considerable during recent years, particularly in America and this country, Dr. Samuel Rideal and his son, Dr. Eric Rideal, have done good service in furnishing us with a handbook that takes into account these modern developments. The chapter on storage affords a good example of the comparatively recent steps taken for the preliminary purification of water by this method. "In the case of London alone the storage has been increased in the ratio of 1 to 6·3 in 24 years." Thus under the eight companies the total storage capacity in 1884 in millions of gallons was 1444·5, whereas in 1908, under the Metropolitan Water Board, the storage capacity was 9156·7 gallons. The water stored in such large reservoirs not only parts with its silt but also with the larger portion of its contained bacteria, the majority being carried down by the silt to which they have attached themselves, and the remainder for the most part perishing for lack of adequate food supply and subsequently sinking. These observations emphasise the importance of storage, and lead to the conclusion that in some cases there may be no need to filter the supply.

In regard to the softening of water the ingenious permutit process is described. This artificial zeolite contains the silicates of aluminium and sodium, and when a hard water is passed through a bed of it, the sodium of the permutit is replaced by the calcium and magnesium of the water which now contains sodium carbonate as an equivalent of the calcium and magnesium salts formerly present.

The chapter on sterilisation is very interesting, and includes valuable references to recent applications, a field in which Dr. S. Rideal has laboured successfully. This is succeeded by an account of electrical modes of sterilisation, including a description of certain installations in which the sterilising power of ozone, electrolytic fluid, the direct current itself, and the ultra-violet light of the quartz mercury lamp are described. The section on analysis and interpretation of results is somewhat short, but, of course, this subject shares little in the main theme of the work. The references to literature are copious, and altogether the book gives a very good insight into the present scientific position of water administration.

MISCELLANEOUS VOLUMES.

IN the preface to the *Manual of Instruction for the Royal Naval Sick Berth Staff* (printed for H.M. Stationery Office. 1914. Pp. 507. Price 2*s.*) it is stated that this book has been written for three reasons: to provide a text-book for probationary sick berth attendants; to promote uniformity of instruction at the naval hospitals; and to provide a concise and comprehensive manual for the sick berth staff in preparing themselves for examination for the higher ratings. These objects have been successfully attained, and it would be difficult to find elsewhere so much useful information on the subjects treated of in an equally compact and inexpensive form. (The analogous manual of medical corps training for the army is also very good, but its scope is different.) In the first hundred pages is given a summary of anatomy and physiology, quite sufficient for the purpose, and well illustrated by 70 figures. A few pages follow on bacteriology, and then the main facts of pathology and treatment are plainly set forth in regard to inflammation, hæmorrhage, injuries, poisons, and the chief groups of diseases, so far as is needed by an intelligent and well-trained nurse. Sick cookery and anæsthetics are dealt with, and a list is given of drugs and appliances, with their properties, doses, and uses. The instructions for stretcher-bearers occupy very little space, and there is much less in the way of drill or routine work than in the analogous medical corps in the army. The book is well printed and illustrated. It is not correct to state that proteids are the only foods that form tissues (p. 92), as fatty tissue is of course largely formed from the fatty food that is eaten and partly also from the carbohydrates. It is also not quite accurate to say that spores of bacteria are killed "by the action of the various antiseptics and disinfectants" (p. 101); there are many useful antiseptics that are not actually bactericidal, though no application is truly disinfectant unless it destroys bacteria and their spores. This book is an official publication and anonymous. The author has been most successful in producing a comprehensive manual, admirably adapted for the purpose for which it was written.——Lieutenant-Colonel R. J. BLACKHAM'S *Indian Home Nursing* (Third edition. Simla: St. John Ambulance Association. 1914. Pp. 235. Price 1 rupee), for the guidance of nurses in India, has reached its fifth thousand, which shows that it has been appreciated. It contains the material for the five official lectures of the St. John Ambulance Association, and deals with all nursing matters in quite sufficient fulness. It is not clear what is meant by the period of exclusion (e.g., 16 days in measles) "from the day disinfection has been completed in the case of infected children." The difference between cocoa and coca might have been explained in a book intended for popular use. The carbonic acid present in air is not 4 per 1000 (p. 16). On the whole the book is very useful and trustworthy.

The latest addition to the Pocket Guide Series, price 1*s.* each, published by the Scientific Press, Southampton-street, London, are *The Muscular System* and *Notes on the Nervous System*, the former by Dr. HAROLD BURROWS and the latter by Dr. EDWIN L. ASH. Dr. Burrows gives a brief sketch of the most important features of the anatomy of the skeletal system, his classification being based upon function, while Dr. Ash summarises the main lines on which the nervous system is constructed. Of course an adequate knowledge of both these subjects can be obtained from standard text-books only, but for revision purposes the pocket guides should prove useful to students, and nurses will probably find in the books all that they need. For the benefit of nurses in particular a chapter on the more common diseases of the brain is appended to "Notes on the Nervous System."

An Index to First Aid, by J. M. CARVEL, M.R.C.S., L.S.A., Hon. Associate of the Order of St. John of Jerusalem (London: John Bale, Sons, and Danielsson. Pp. 135. Price 1*s.* net), is described as a vade-mecum for the ambulance worker and all interested in the subject of first aid to the injured, its purpose being to indicate briefly the correct line of action to be adopted by the "first aider" in any particular case, this being facilitated by an alphabetical arrangement of subjects. Such an index of terms and treatment may conceivably be useful to ambulance workers pending the arrival of a medical man, and also as a ready means of refreshing the memory for purposes of study, but the first aid worker if he is to be of real use should have his knowledge at his finger ends. The book is illustrated and interleaved with blank sheets for memoranda.

JOURNALS.

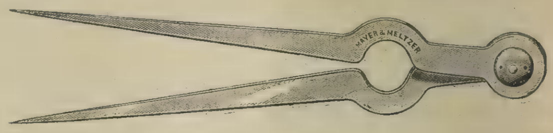
The Indian Journal of Medical Research, Vol. II., No. 2.—This number contains 12 original articles, the first two of which deal with the subject of malaria, one being contributed by Captain E. C. Hodgson, I.M.S., on the incidence of the disease in the recently constituted province of Delhi, illustrated by photographs, maps, and charts; the other by Major E. L. Perry, I.M.S., treating of the endemic malaria of the Jeypore Hill Tracts of the Madras Presidency. Major Perry's paper is illustrated by several plates and diagrams and a map.—The next article is by Captain W. S. Patton, I.M.S., of the King Institute, Madras, who gives the results of the examination of the peripheral blood of 84 patients suffering from kala-azar in the General Hospital at Madras during the 12-month period ended July 15th, 1913.—Two other papers deal also with kala-azar, and both are contributed by Major F. P. Mackie, I.M.S. The first, with a map, describes the progress of the disease in a localised community in the endemic area situated between the Brahmaputra River and the Garo Hills, this region being the oldest known focus of kala-azar in the province of Assam. The second is a note, with an illustrative plate, on some bodies of unknown nature found by Major Mackie in the fæces of kala-azar patients in Assam. This officer has for some time been engaged in investigating the malady in this region, and his note raises the suggestion that this form of leishmaniasis may after all be spread by means of the intestinal discharges of the patient and not by a blood-sucking insect; but obviously further researches are required before any conclusion upon the matter can be reached.—Major A. C. MacGilchrist, I.M.S., in continuation of his previous work, furnishes a third communication on his cinchona derivatives inquiry, giving a synopsis and discussion of our present knowledge of the molecular constitution and pharmacological action of the more important of the cinchona derivatives.—Some observations on the salivary secretion of the common blood-sucking insects and ticks are contributed jointly by Major J. W. Cornwall, I.M.S., of the Pasteur Institute, Coonoor, and Captain W. S. Patton, I.M.S., of the King Institute, Madras.—A culturable, free-living flagellate, and the determination of the lethal value of certain chemicals thereon, form the subject of an article, which is illustrated by a coloured plate, by Dr. Gopal Chandra Chatterjee, assistant bacteriologist at the Medical College, Calcutta. The flagellate in question was found by Dr. Chatterjee in water taken from a tank, and it grew in ordinary bouillon and peptone water in intensely rich culture. The author regards it as possibly a new species of the sub-family Trypanoplasma of the Flagellata.—Major E. D. W. Greig, I.M.S., who has been employed for some time past upon the systematic study of cholera, supplies two papers to this number of the *Journal*, the first dealing with the simultaneous occurrence of cholera and cholera-like vibrios in the tissues of persons suffering from the disease; and on this part of the subject he promises a further contribution at a later date. His second paper is on the hæmolytic action of Indian strains of cholera and cholera-like vibrios.—A joint article by Major W. F. Harvey, I.M.S., and Captain H. W. Acton, I.M.S., treats of methods of estimation of quantity of organisms in suspension, the organism chosen for this investigation being the dysentery bacillus.—Lastly, Major Clayton Lane, I.M.S., gives a detailed description, with eight illustrative plates, of suckered round-worms found in India and Ceylon.—This number maintains well the high practical and scientific standard set by the articles already published in the *Journal* by the officers of the Indian Medical Service.

British Dental Journal.—The issue for March 1st contains an article by Dr. J. H. Sequeira on oral affections from the dermatological standpoint. After referring to syphilis he draws attention to oral tuberculosis and lupus, and then discusses the possible relationship of the erythemata to oral sepsis. Jacquet's hypothesis that alopecia areata was intimately associated with trigeminal irritation does not, he thinks, stand the test of careful clinical investigation.—Mr. W. H. Dolamore has a short note on the value of metal "cap splints" for the treatment of fractured mandibles. He draws attention to several practical points in their manufacture and adaptation, and speaks highly of the results obtained from their use.—Mr. A. Barrett contributes an article on the antiseptic and germicidal value of ether, and Mr. Valentine Kay one on the treatment of cysts.

New Inventions.

BONE GRAFT CALLIPERS.

IN performing a bone-grafting operation it is necessary to have some ready means of accurately measuring the extent of the bed the proposed graft is to occupy. The instrument here illustrated I have found exceedingly useful. It presents three advantages: (1) The character and size is such as to obviate the necessity of introducing the fingers into the wound—a desirable aim in all bone surgery; (2) after the measurement is taken the callipers can be laid aside, without any chance of losing the exact distance ascertained; and (3) the sharp points conveniently mark the limits of the graft in the periosteum of the bone chosen—usually the inner surface and crest of the tibia.



The instrument has been made for me by Messrs. Mayer and Meltzer, Great Portland-street, London, W.

HARRY PLATT, M.S. Lond., F.R.C.S. Eng.,
Surgeon to and Surgeon in Charge of the Orthopædic Department, Ancoats Hospital, Manchester.

ISOLATION HOSPITALS IN CORNWALL.—The Local Government Board has recently requested the Cornwall County Council to consider the inadequate isolation accommodation in the county, especially in view of the likelihood of outbreaks of infectious diseases when soldiers return from the front. The medical officer of health states that, excluding small-pox hospitals, there are nine isolation hospitals in the county and 33 districts are quite unprovided for. A special meeting of the council was accordingly held last week, at which a committee was appointed to consider the subject.

CENTRAL MIDWIVES BOARD.—A special meeting of the Central Midwives Board was held at Caxton House, Westminster, on March 12th, Sir Francis H. Champneys being in the chair. A number of midwives were struck off the roll, the following charges amongst others having been brought forward: Not observing the antiseptic precautions prescribed by Rules E. 3 and 7; neglecting to cleanse the child's eyelids as prescribed by Rule E. 15; being unable to take and record the pulse and temperature of patients, as required by Rule E. 13; not keeping the register of cases as required by Rule E. 23; and the midwife refusing to give to the inspector of midwives reasonable facility for the investigation of her mode of practice, as prescribed by Rule E. 24. The midwife not keeping her appliances in a cleanly condition, as required by Rule E. 1; not possessing the appliances and antiseptics required by Rule E. 2; and, in spite of repeated warnings, failing to comply with the rules of the Central Midwives Board. Neglect to disinfect the hands and forearms, as prescribed by Rule E. 3; neglect to wash and swab the patient's external parts prior to the confinement, as required by Rule E. 7 (a); washing the patient with dirty water during the lying-in period, and neglecting the antiseptic precautions required by Rule E. 7. Medical aid having been sought for a patient, the midwife neglected to send any notification thereof to the local supervising authority, as required by Rule E. 21 (1) (a); being under the influence of drink on more than one occasion when attending a patient, and not being scrupulously clean, as required by Rule E. 1.

THE LANCET.

LONDON: SATURDAY, APRIL 3, 1915.

Health and Occupation.

AT a recent meeting of the Eugenics Education Society Sir ARTHUR CLAY read a paper on Eugenics and the Poor-law, in the course of which he touched on some problems of peculiar interest at the present moment. Having pointed out that the great war in which this country is now engaged is a severe test of the national character, he showed that it is therefore in some measure a test also of the value and efficiency of the various social agencies which directly or indirectly affect the vigour and the vital energies of the population. Of these agencies the Poor-law is one of the most influential, and we may accordingly expect that the reaction of pauperism to the strain of the war will be found to be one of the most instructive and illuminating sociological phenomena arising out of the present crisis.

It will not, of course, be possible for some considerable time to determine the nature and extent of this reaction, but we can already see various indications which warrant us in anticipating that the experience of war will strongly support the view that part, at all events, and probably a large part of the destitution dealt with under the Poor-law is of an artificial and unnecessary character. This, of course, is no new discovery; it has always been recognised that the administration of public relief can be so conducted as to modify very considerably the amount of pauperism, that, as it has been put epigrammatically, "a nation can have as many paupers as it chooses to pay for." But in the present instance we are enabled to see rather more deeply into the biological conditions which allow of this response to pauperising influences, or, as it may be expressed in less special terms, to the influences making for the physical and moral enfeeblement of the population. And we then find, as has been found in respect of other social phenomena under the test of the national struggle for existence, that one of the important lessons to be learned from this war is that under our present social system there is a great deal of preventable waste, that the community does not get the best value out of the individuals composing it, because of the very imperfect adjustment of opportunity to aptitude. As an illustration of this point reference may be made to the effect which the war appears to have had on the general health of the non-combatant population in this country. It was pointed out, for instance, at a recent meeting of the Governors of the Royal Sussex County Hospital at Brighton, that since the commencement of the war the health of the civil population of that town, judged by the demands for hospital treatment, had improved so much that it was possible to make liberal provision for the reception of wounded soldiers without putting any strain on the resources of the institution. And similar observations have been made in other parts of the country, both in regard to general hospitals and in regard to asylums for the insane; though in the latter case the decrease seems to be confined to males, the number of female admissions even showing a slight rise. No one, of course, would think of suggesting that this curious change is due to any directly beneficial influence of the war-like spirit, or that the ultimate effect of a long and fiercely contested struggle under the conditions of modern warfare is likely to be anything but detrimental to the physical and still more to the mental health of the belligerent nations. But it is instructive as showing—for that seems to be by far the most probable explanation of the fact—that the economic readjustments necessitated by the outbreak of hostilities have recalled to activity, and therefore to healthier existence, a considerable number of individuals who under ordinary circumstances would have been nursing their minor ailments. The older and feebler men who were taken on to fill the places of the young and robust recruited for active service have improved in health when once more in regular work and well fed, and they have benefited also, no doubt, by the stimulating sense of being again useful members of the community, especially at a crisis that has greatly exalted the intensity of the social consciousness. Many of those who have been recalled to active employment were probably men whose main disability was the largely conventional one of years. They laid aside their vocations merely on account of having reached a certain age, and, having no particular interest or pursuit to which to turn, inclined to despondency and premature dotage with their concomitant ailments. COWPER sums it up very neatly when he says:

> Absence of occupation is not rest,
> A mind quite vacant is a mind distressed.

To impose idleness upon men merely because they have attained a certain age, or in conformity with a fixed rule in the particular sphere of labour in which they may be engaged, is injurious to the individuals so treated, and is wasteful from the point of view of society. The wrench of enforced leisure when in the prime of life causes premature decay and wretchedness, bringing on permanent ill-health, while a continuously occupied mind favours a ripe old age. In occupations that are not subject to these artificial rules, and most conspicuously in the higher walks of professional life and in the life of the creative artist or the scientific investigator, there is no such abrupt and compulsory cessation of activity, and therefore, too, there is as a rule no phase of premature decadence of mental and bodily powers, no long drawn-out period of ailing inutility.

If, then, we are correct in concluding that our present social and industrial system, by reason of the under-occupation which it enforces on the older and less robust members of society, is an important factor in producing the graver impairment of physical and mental vitality which is responsible for much of the pauperism and ill-health in the community—if that conclusion is justified, we may, perhaps, hope that in the period of reconstruction which must follow the war some effort will be made to devise a less wasteful method of utilising this human material. As matters stand, any decrease in a workman's industrial efficiency, due to advancing years or physical infirmity, tends ordinarily to withdraw him altogether from useful activity in his regular employment, with the result that the value of his acquired skill and technical experience is entirely lost to society, while the man himself suffers in mind and body through being forced to turn to unfamiliar, worse paid, and less interesting forms of labour. Such a system is obviously bad for the community and bad for the individual.

◆

Treatment of Wounds in War.

IN Sir WATSON CHEYNE'S recent Hunterian Oration[1] he gave a preliminary account of investigations which were being carried on by a committee appointed by the Medical Department of the Navy to investigate the question of the immediate treatment of wounds in war. At that time a variety of antiseptics were being examined, among others salicylic acid, but the results obtained with that substance were not sufficiently definite to warrant any special reference to it in the oration. A more detailed account of the investigation will, however, be published immediately in the April number of the *Journal of the Royal Naval Medical Service*, from which it appears that salicylic acid is likely to prove a valuable agent in the treatment of these wounds. Experiments on guinea-pigs with highly infected earth containing large quantities of tetanus bacilli and also of the bacillus aerogenes capsulatus have yielded, shortly, the following results. All control animals died in 30 to 36 hours as the result of infection with the latter bacillus, but those which lived longer as the result of various methods of treatment developed tetanic symptoms. Where the earth was mixed before inoculation with a powder of equal parts of salicylic acid and boric acid (called for shortness bor-sal) no illness resulted. The majority of the animals, in which 5 to 15 minutes after the infected earth was rubbed into the wound the wound was filled up with bor-sal powder, recovered; but where the bor-sal was made into a paste with gum tragacanth the results were not good, possibly, for one reason, because the amount of bor-sal introduced was smaller. Where, after infection with the earth, the wound was in the first place filled up with bor-sal powder and half an hour later with cresol paste (20 per cent.), all the animals recovered and the wounds healed without suppuration. Where bor-sal powder was applied first and antitetanic serum was injected afterwards, all but one of the animals recovered. The committee recommend provisionally that the wounds should be thickly powdered with bor-sal powder, and that the 20 per cent. cresol paste should then be introduced into all the recesses of the wound as soon as possible after the infliction of the injury, and in cases where the wound is soiled with earth antitetanic serum should be given. Steps are being taken to distribute dredgers containing one ounce of bor-sal powder, and tubes with long nozzles containing half an ounce of 20 per cent. cresol paste, to all the ships in the navy, and in case of landing parties each man will be provided with these as well as with the first-aid dressings. This preliminary treatment can be carried out in a very short time and, except in abdominal and thoracic injuries, by anyone who has been instructed, and it is hoped that it may prevent serious infection during the interval which elapses before the wound can be more thoroughly disinfected. If a large number of wounded are received at one time, the orderlies could renew the powder and paste and bandage while the surgeons are attending to the most urgent cases. The more careful disinfection will consist in cleansing the wounds, removing foreign bodies such as pieces of clothing or shell, which may be easily accessible, washing out the wounds with 1–20 carbolic lotion thoroughly, drying them, and then powdering them again with bor-sal, putting in fresh cresol paste; in the case of large wounds a few interrupted stitches will prevent the antiseptic escaping too quickly. A wound so dressed may not require further dressing for a considerable time. These recommendations are, of course, only provisional, and may be varied as the result of experience or of the investigation of other antiseptics, but in the meantime the above suggestions seem worthy of a thorough trial. Those who are interested in the matter will find full details in the forthcoming number of our Service contemporary.

DONATIONS AND BEQUESTS.—The late Mr. Alexander Elder, of the Elder Dempster Steamship Line, left £100,000 upon trust to found, equip, or endow a hospital for the poor of Govan, at or near the Elder Park, Govan, to be known as the "David Elder Infirmary" (in memory of his father); £50,000 to the Western Infirmary, Glasgow, for a new wing, to be called the "Alexander Elder Wing"; £3000 to the Southport Infirmary; £2000 each to the Southport Convalescent Hospital and Sea Bathing Infirmary and the Royal Southern Hospital, Liverpool; £1000 each to Dr. Barnardo's Homes and the Liverpool Maternity Hospital and Ladies' Charity. The residue of his estate will be divided, at the discretion of his executors, among certain charitable institutions, including hospitals, in Liverpool and Glasgow.

---

Annotations.

"Ne quid nimis."

THE ROYAL COLLEGE OF PHYSICIANS OF LONDON: ELECTION OF PRESIDENT.

AN extraordinary Comitia of the Royal College of Physicians of London was held on March 29th, Sir Thomas Barlow presiding and delivering the usual Presidential Address, in the course of which he referred to the honours that had been conferred on Fellows, Members, and Licentiates during the year. He especially mentioned Captain A. M. Leake, R.A.M.C., who for the second time had been awarded the V.C. He also reviewed the list of the lecturers of the year, the gifts which had been made to the College, and the medals and scholarships which had been awarded. After consideration of the principal matters which had been discussed at the College, the President read obituary notices of the Fellows who had died during the year—namely, Samuel Herbert Habershon, Edward Cox Seaton, Isaac Burney Yeo, Eustace Smith, John Abercrombie, and Philip Henry Pye-Smith. In conclusion, the President thanked the censors, the officers of the College, and the Fellows for the support they had given him during the time he had occupied the presidential chair. Dr. P. W. Latham proposed a vote of thanks to the President for his address, with a request that it might be printed; he added that the Fellows wished to express their highest appreciation of Sir Thomas Barlow's services to the College whilst President. Sir Thomas Barlow thanked the College and vacated the chair. The ballot then took place for the election for President, and Dr. Frederick Taylor was elected. The Senior Censor, Dr. Percy Kidd, delivered the charge and handed to Dr. Taylor the insignia of office. The new President then gave his faith to the College and expressed his thanks for the honour conferred on him.

THE AIR AS A SOURCE OF EXPLOSIVES.

THE demand recently credited to Sir John French, "Munition, more munition, always more munition," may well have been "Nitrogen, more nitrogen, always more nitrogen," for without nitrogen the most distinctive form of modern munition—namely, the high explosive—cannot be made. There is a vast importance attaching to this element just now; it possesses, as a matter of fact, in time of peace an equal importance, inasmuch as it is an essential constituent of our foods, but until the manufacture of explosives became a matter of national urgency the public was prepared to explain the statement of chemical text-books, which are wont to describe nitrogen as an inert element, as meaning an element of no activity. Ordinarily speaking, nitrogen is comparatively an inert gas; great forces only can find for it affinities; it will not combine under simple circumstances, nor does it exhibit simple characteristics in the same way as the other gases do, as, for example, oxygen, hydrogen, or chlorine. Of course, to some extent it is this very inertness which renders nitrogen a powerful explosive agent. So to speak, it yearns to be free, and a small temptation releases it from the combination in which it is an unwilling partner. It is harmless enough in the air, and we breathe it with impunity every minute of our lives. Yet the future will most likely show that the great foundation of explosives will be the air itself. The world's supply of nitrogen in the form of nitrate has been hitherto derived from the beds of this salt occurring in Chili, and something like 400,000 tons of nitrogen in the form of nitrate are annually exported from that country. But the same quantity occurs in the air over every 13 acres of ground, and the summarising calculation has been made that the whole atmosphere of the world contains 4000 billion tons of nitrogen. In explosives nitrogen may be said to play two parts: it carries in essential oxygen, and then is itself released on combustion in a highly expanded gaseous state. The nitrification of hydrocarbons of the benzene type (toluol) and of phenols supplies the modern explosive. If the issue of war is to depend upon explosives that nation will win who succeeds in utilising the greatest supply of nitrogen, and this consideration has led to some interesting speculations. Should the nitrogen of the air become economically available for the purpose all nations will be equally well off as regards the supply of raw material. The important question remains, however, as to whether all nations will be equally well situated concerning the means of converting this abundant supply into nitric agents. It is only economic power that can do this for practical purposes, and, so far, water power is the cheapest producer of nitric acid from the air. The process is simple, but requiring great energy. If the temperature of the air is raised to an intense degree a point is reached when nitrogen begins to burn and nitrous acid and nitric acid are formed. The necessary temperature is reached by the electric arc flame. The arc flame is most economically produced by water power. Thousands of tons of nitric acid are produced in this way in Norway and Sweden. If bombs and shells, therefore, are to be regarded as the decisive factor in a war, a limited view which we are certain that Sir John French does not take, the nation will win the struggle which can produce the greatest output of these weapons. Assuming that no cheaper method of production than by water power converted into electric energy is available, and assuming again that equally effective explosives of a non-nitric type are not invented, this conclusion affords a suggestive perspective when the countries which possess great natural water powers and great gasworks are remembered. Nitric acid requires partners, and the most effective are produced at the gasworks. As far as we know, carbolic acid and toluene are produced nowhere else in practical quantities, so that the gas industry assumes an importance equal to the great water-power stations when the production of explosives is considered.

THE MEDICAL INSURANCE AGENCY.

AT a meeting of the committee of the Medical Insurance Agency, under the chairmanship of Dr. G. E. Haslip, which was held at the offices of the British Medical Association on Wednesday, March 24th, a report of the work of the agency during the year 1914 and the audited balance-sheet were submitted to the committee by the chairman. Both the balance-sheet and the report were approved by the committee, and with good reason, as the working of the year was seen to be highly successful. The total sum of money received during the year from premiums and other sources amounted to over £10,000, the premium income showing the valuable connexion which has been established in a comparatively short time. The actual commissions earned enabled something over £300 to be ear-marked for distribution. It may be remembered that the committee distributed £315 in November last in medical benevolence, and if its efforts are supported there is no doubt that its annual contributions will become a powerful factor in the support of our professional charities. The chairman advised in the report that it would be prudent not to distribute more than £200 of the surplus money, having regard to the uncertainties created by the war, and it was resolved that the following grants should be made, totalling £200: The Royal Medical Benevolent Fund, £75; the Royal Medical Benevolent Fund Guild, £50; Epsom College Benevolent Fund, £50; and the Royal Army Medical Corps Benevolent Fund, £25. The fund has now distributed during its short life £1275 to medical charities, while returning to insurers by way of rebates £3700. The committee has every reason to be proud of what it has accomplished, and to look forward to a greater sphere of work and utility. The energy and tact of Dr. Haslip, who has given much time and trouble to the work, deserves full recognition.

LEPROSY IN HAWAII.

SINCE 1909 a new law has been in force in Hawaii making the apprehension and detention of lepers compulsory. Every person who has reason to believe that he or any other person not under control by the state is a leper must forthwith notify the fact to the Board of Health; and anyone so reported must be examined medically, after which, if the diagnosis be established, he must be duly isolated. Notwithstanding this law difficulty is still encountered in securing the discovery of every case of the disease. In a statistical study of leprosy in Hawaii recently published in the *United States Public Health Bulletin*, No. 66, Dr. George W. McCoy gives some interesting particulars regarding the malady in this American dependency. The total number of lepers officially apprehended since 1901 has amounted to 1060, or an annual average of about 82. Of this total, 52 were Portuguese, 14 belonged to other European nationality, 13 were Americans, 29 Japanese, and 61 Chinese. About half of those apprehended were between the ages of 11 and 25 years. It is a curious fact that the incidence of the disease is almost twice as high among males as among females, the respective figures being 673 and 387. Inquiry into the previous history of the cases showed that association with leprous persons was admitted in nearly 37 per cent., and in this number the presence of the malady in a parent, brother, or sister constituted over half of the admitted association. Dr. McCoy believes that the statement frequently made—namely, that prolonged and intimate contact with leprosy is needed to bring about infection—is certainly not borne out by the facts as witnessed in Hawaii. Cases are frequently met with in which there is absolutely no history of any association with lepers. Difficulties often arise with regard to the early diagnosis of the disease before apprehension of the patient. In 188 cases the leprosy was alleged to have existed less than a year, in 131 for a whole year, in 99 for two years, in 92 for three years, in 48 for four years, and in 42 for five years. In 86 it had existed from six to 10 years, and in 49 for more than 10 years. In 20 instances it was claimed that the disease had existed the whole of the lifetime. The statement sometimes made that the malady has persisted from infancy is generally put forward for the purpose of misleading the investigator. It is encouraging to learn that the percentage in recent years of lepers apprehended early is larger than formerly. As regards the finding of the bacillus lepræ at the official medical examination, this was positive in 929 cases; in 60 it was negative, and in 71 instances no information on the point was given. It appears that nodular cases now form a larger proportion of the whole than in the past; 327 patients suffered from the anæsthetic type of the malady, 384 from the nodular, and 275 from the mixed. In 74 instances the type of leprosy was not recorded. The control of the disease places a heavy financial burden on Hawaii, and at present there is little likelihood of its becoming lighter in the future. We learn that the legislature appropriated the sum of $412,130 for the care of lepers, including permanent improvements, for the two-year period beginning July 1st, 1913.

ANTISTREPTOCOCCIC SERUM IN ACUTE BRONCHITIS.

IN another column we publish a note by Mr. J. G. Hayes on the use of antistreptococcic serum in acute bronchitis. In the three cases which he records relief followed the administration of the serum. It would be unwise to attempt to draw any conclusions from such a small number of cases; a much larger field for research would be necessary. Nevertheless, the publication of only a few cases treated by any special method may have some value as indicating the results arrived at by a particular observer, for such results may be corroborated or contradicted by other workers. Thus accumulative evidence may be obtained, which eventually may lead to a decision in respect of a therapeutic measure. It has frequently been stated that to base an opinion of any form of treatment on the observation of only a few cases can only be fallacious, and probably many observers would challenge Mr. Hayes's conclusions. The bacteriology of acute bronchitis appears to vary, and that the toxæmia of acute bronchitis is in most cases due to a streptococcus is by no means certain; the pneumococcus is also found, and in such cases antistreptococcic serum would not be indicated. If Mr. Hayes's lead is followed, it would be well to place the treatment on a more scientific basis by a bacteriological examination of the sputum before the treatment is commenced, so as to isolate, if possible, the pathogenic organism.

GERMAN PROSTITUTES IN BELGIUM.

AMONG the many questionable benefits conferred by German Kultur on Belgium appears to be a large number of syphilitic German prostitutes. So wrote the Antwerp correspondent of the Dutch journal *Het Telegraaf* a few weeks ago, commenting on the statement of the German Catholic paper, the *Kölnische Volkszeitung*, that about 180,000 cases of venereal disease had occurred in the German armies in Belgium and Northern France. The German paper made the assumption that the sources of infection were to be found among the inhabitants of the invaded countries.

The Antwerp correspondent, however, throws quite another light upon the actual state of affairs. In Belgium, as he points out, prostitution is most carefully and systematically regulated and controlled, submitted to registration and inspection; cases of venereal disease are at once submitted to hospital treatment until they are no longer infectious. Prostitutes of alien nationality are expelled and made to return to their own countries; in the case of Antwerp, over 80 per cent. of the prostitutes thus expelled are German women. If the German military authorities wish to put a stop to the prevalence of venereal disease among the German soldiers they should expel from Belgium the German sources of infection, bringing into force once more the Belgian enactments for the regulation of prostitution. The matter is not without interest for the Allies at the present moment. It is to be expected that they will be advancing along the Western battle-front before many weeks are past, and there seems to be good reason for fear lest the Allied troops and the returning inhabitants should be unduly exposed to infection with venereal disease when the country at present held by the Germans is cleared of its invaders and returns to the possession of its rightful owners.

TONIC INNERVATION.

Dr. S. A. K. Wilson describes in *Brain* (vol. xxxvii., 1914) under this title a curious, and apparently not very common, clinical condition which he has observed in three cases. Briefly, the symptom consists in inability to relax the muscles which have performed a "willed" or voluntary action, whilst direction of the subject's attention away from the act immediately "unlocks," as it were, the sustained effort. In the cases instanced the phenomenon was strictly unilateral, and involved mainly the arm muscles. There was, in all, involvement of the cortico-spinal path; in two cases the lesion was a tumour situated in, and successfully removed from, the right hemisphere. There were slight spasticity and active reflexes in the affected limbs. No sensory changes were noticeable. Tonic innervation, Dr. Wilson suggests, must be distinguished from certain examples of sustained or clonic performance of an act other than the one demanded of the patient, as also from "ideational inertia" of purely psychic origin. It may or may not be associated with apraxia (or simple inability to perform movements which automatically could be executed without difficulty), again a condition of psychic origin. The symptom is regarded, in short, as of psychomotor origin—dependent on psychic changes, especially volition, in that this element, whilst not *per se* the cause, at any rate influences the act in an obvious manner; dependent upon motor changes in that the symptom is only observed when the specific functions of the cortico-spinal tract are slightly impaired. It is noted that when the pyramidal lesion is more evident, the symptom goes; the pyramidal involvement, it appears, must not be too great. That tonic innervation is not attributable to muscle changes is suggested by the strong evidence that its contraction is of the type recognisable by galvanometric observations as characteristic of centrally innervated activity, evidence gained especially in myotonia cases which present certain clinical similarities to the condition under consideration. Where is the lesion, and what is its character? It is said to be extremely likely that the phenomenon of tonic innervation is due to a disturbance of reciprocal innervation in "willed" movements; with such disturbance the relaxation of the antagonistic muscles to those performing an act is interfered with. But this reciprocal innervation may be carried out in spine or in cortex. In the cases here recorded it is suggested that there was impairment of function of the cortico-spinal neurones from a lesion at their cortical end ...... "either the activity of the affected motor centres is directly interfered with or, more likely, the stimuli reaching them by short transcortical paths from a hypothetical psychomotor centre placed in the area in front of the precentral gyrus are interfered with." Finally, it is probable, since few cortical lesions demonstrate the sign, that a certain stage in the functional interference must be maintained.

ANNUAL CONGRESS OF THE OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

THE annual congress of the Ophthalmological Society of the United Kingdom will be held on Thursday to Saturday, April 22nd to 24th. On Thursday morning papers will be read at the Royal Society of Medicine, 1, Wimpole-street, W.; at the afternoon sitting a discussion on Ophthalmic Injuries in Warfare will be opened by Mr. W. H. H. Jessop and Colonel W. T. Lister; at 5 P.M. the annual business meeting will be held. Friday morning will be devoted to a discussion on Detachment of the Retina, to be opened by Dr. A. Maitland Ramsay, Mr. Leslie Paton, and Mr. M. S. Mayou; in the afternoon there will be a clinical meeting at the Royal London Ophthalmic Hospital, City-road, E.C. On Saturday morning papers will be read. Members desirous of reading papers or showing cases should communicate at once with the honorary secretary, Mr. G. Coats, 50, Queen Anne-street, W. It is intended to hold an exhibition of drawings, specimens, and so on, during the meetings. Exhibits should be addressed to Mr. M. S. Mayou, 30, Cavendish-square, W.

A RECEPTION will be held by the West London Medico-Chirurgical Society at the West London Hospital on Friday, April 23rd, at 8.30 P.M., when the programme will include war exhibits, short addresses on war subjects, illustrated by lantern slides and pictures, and music. The charge for each ticket, whether for a member, a lady, or other guest, is 5*s.*, and it is hoped that members of the society will subscribe even if they are unable to be present for the whole of the proceeds, after the deduction of expenses, will be transmitted as a donation from the society to the Belgian Doctors' and Pharmacists' Relief Fund. Early application for tickets, enclosing a remittance, should be made to either of the honorary secretaries, Mr. Oswald Addison, 125, Harley-street, W., or Dr. Reginald Morton, 66, Harley-street, W.

AMONG the Fellows of King's College, London, appointed on March 24th, occur the names of Sir Arthur William May, K.C.B., Director-General of the Naval Medical Service, and Sir Arthur Thomas Sloggett, K.C.B., C.M.G., Director-General of the Army Medical Service.

Colonel Sir W. B. Leishman, R.A.M.C., was personally invested by the King on March 29th at Buckingham Palace with the Insignia of a Companion of the Bath (Military Division).

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE FUND AND RELIEF MEASURES IN BELGIUM.

AT the last meeting of the Executive Committee of the Fund full information was forthcoming concerning the urgent needs of the Belgian doctors and pharmacists remaining in their own country, and at the same time a plan was considered and adopted for attempting through the medium of the Fund to alleviate this distress. In Belgium the committee formed to consider the position of the doctors and pharmacists has now been largely reinforced, and is known as the Aide et Protection aux Médecins et Pharmaciens sinistrés. The President is Dr. Péchère and the secretary M. Delacre. The body is a representative one, and has organised machinery for ascertaining where the need among those whom it would help is greatest and for providing systematic relief. It has worked in connexion with the National Relief Fund and has received from that Fund a subsidy, which is now exhausted. When the Belgian Committee was started Professor Jacobs, professor of obstetrics in the University of Brussels, came to England last November as its delegate, and it is owing to the representations which he then made that the movement in this country, and later in our dependencies and in America, was started. The Executive Committee of the Belgian Doctors' and Pharmacists' Relief Fund has always said, in appealing for subscriptions, that a part of the money which it might collect should, as early as the conditions in Belgium permitted, be distributed on the advice of the committee in Belgium. At first, however, no method of communication between ourselves and a country mainly occupied by the enemy's army was possible. Through the good offices of Mr. Herbert Hoover, the Chairman of the National Relief Fund, we were able to distribute some medical material, which was conveyed to its destination by the National Fund, but at that point we were compelled to remain until some effective machinery on the other side rendered more substantial and fruitful coöperation possible. The Aide et Protection aux Médecins et Pharmaciens sinistrés has now prepared the ground, and done so with great energy despite the immense difficulties under which it has had to work. Forms have been issued to all the doctors and pharmacists in Belgium on which they are asked to state frankly their position, that of their families, the loss that they have sustained, and the amount of money necessary to enable them, at any rate, to tide over their existing terrible circumstances. In estimating the validity of the claims the Belgian Committee has acted in consultation with the local medical societies throughout Belgium and with the Government inspectors of pharmacy, who also inspect the dispensaries of medical men. Those who have been relieved include the widows of doctors and pharmacists who have fallen fighting, or who have been the victims of German ferocity. It is noteworthy that such money as has been hitherto given has been given entirely to the country at large, although distributed from Brussels; in Brussels the better circumstanced doctors and pharmacists have supported the Fund for the relief of their poorer colleagues. Many of the forms relating to the pharmacists have reached this country and have been submitted to the Executive Committee of the Belgian Doctors' and Pharmacists' Relief Fund, and it is hoped that we shall later receive the forms relating to the medical men; but enough evidence has been submitted to the Executive Committee to enable it to realise that immediate help in money ought to be sent as this now seems feasible. With the coöperation of the banks concerned a sum of money is being sent immediately to Belgium to be distributed by the Aide et Protection aux Médecins et Pharmaciens sinistrés in accordance with the particularised needs which are now in the hands of that body; and it is proposed to send further sums from time to time as detailed reports from the Belgian Committee and other information at the disposal of the Executive Committee show that the money is being usefully expended. Subscribers to the Fund will see that the Executive Committee has now embarked upon a definite scheme of large expenditure, and, generous as the responses have been to the appeal by British doctors and pharmacists, it will be necessary that further effort should be made, and even made with greater vigour than heretofore. The Fund can do much with the money which it has in hand, but it is not possible to estimate how long the strain upon it may have to be maintained, and far greater resources than it possesses will be urgently required.

THE GIFT OF INSTRUMENTS TO BELGIAN MILITARY HOSPITALS.

It will be remembered that through the medium of Mr. S. Osborn a selection of the instruments, which have been received by Mr. Meredith Townsend, the Master of the Apothecaries' Society of London, in response to the appeal of the Fund, was placed at the disposal of certain Belgian military hospitals. Sir Rickman Godlee, the chairman of the Executive Committee, has received from Captain G. Deffontaine, writing for the Belgian Military Command in Calais from the Hôpital de Passage, a cordial letter of thanks for the instruments, while Mr. Osborn has reported to Mr. Townsend that the instruments arrived at a particularly opportune moment, when a fire had burnt out the operating theatre of the Hôpital Jeanne d'Arc.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge with thanks the receipt of surgical instruments kindly contributed by Dr. J. Jones, of Leigh, Lancashire.

THE WEEK'S SUBSCRIPTIONS.

Owing to Easter THE LANCET went to press early, and the detailed list of subscriptions for the incomplete week will be published in our next issue.

THE QUEEN AND THE LONDON SCHOOL MEDICINE FOR WOMEN.—The Queen, accompanied Princess Alexander of Teck, paid an informal visit to the London School of Medicine for Women, Hunter-street, W.C., on March 24th, when Her Majesty was received by Miss L. B. Aldrich-Blake, dean of the school, Dr. Mary Thorne, Mrs. Scharlieb, and Miss L. M. Brooks, secretary and warden. Her Majesty showed great interest in the work of the students, in the site for the new extension of the school, and in the plans for the new women's military hospital which will be opened in April in Endell-street.

THE WAR AND MEDICAL PRACTICE AT SOUTHAMPTON.

(From our Special Commissioner.)

Southampton, March 22nd.

When it has been necessary to organise the medical profession for some common purpose the practitioners of Southampton have always shown themselves active. In the old days of the Battle of the Clubs they were well to the front. Indeed, so energetically was this battle fought that the medical aid societies and the various financial schemes based on the exploitation of medical men obtained no hold in the town. Accustomed to act in concert the practitioners of Southampton were prompt to meet to discuss the professional situation created by the war directly it was declared. On the day itself, August 4th, they held a meeting, and by August 5th a circular had been drawn up, printed, and sent round to every medical man in the district. Their action was impulsive, patriotic, and generous; whether it was altogether wise is now being discussed. The one dominating thought at the outbreak of war was that nothing should stand in the way of the practitioner whose services might be wanted at the front. Therefore all the practitioners were informed that during their absence their colleagues would look after their practices. It would be a point of honour not to attempt to capture the absentee's patients. On his return, not only would the patients be restored to him, but also he would receive all the fees which they had paid during his absence. Thus the profession at Southampton pledged itself to work gratuitously for those of its members who were mobilised. What this might entail was obviously not foreseen at the time. The fact is that the medical profession, like most other sections of the community, could not realise what war on a continental scale would mean.

The Private Practices of Surgeons with the Colours.

A small army or expeditionary force is one thing, an armed nation is a very different matter. If we had raised an extra force of half a million only above our normal or regular army the generous proposal of the Southampton practitioners might still have been practicable. But the figures now reached by our army make the economic results of the Southampton project well-nigh impossible. Before anything like the number of men now with the colours had been enrolled the effect on panel practice was marked. This, as in the case of all contract work, depends for its financial feasibility on the percentage of sound lives among the lists of insured persons, Now it is just these sound lives, the very best of them, who are enlisting; and as a panel doctor pathetically put it to me, "they leave the crocks behind." A large proportion of the new armies in course of formation consists of men who were insured, and being healthy and in the prime of life they gave their panel doctors very little trouble. To-day, it seems, panel practice means nearly the same amount of work as before the war, though there are fewer insured persons to pay for it. If, also, a panel practitioner finds he has to attend for nothing the paying patients of a fellow practitioner who has gone off to the war, he feels sore. So long as only one or two practitioners thus left their practices to the care of their colleagues, and this work was divided between several, it did not matter very much. But we have passed that stage. As the war continues and the demand for more troops ever increases the difficulty becomes apparent, and at Southamptom some medical men are already thinking that perhaps the arrangement was too hastily made. Certainly a practitioner should not lose his position, acquired perhaps after a long struggle, because in his sense of duty he has gone to the war. But if this practitioner is paid for his services in the army, and as well paid as if he had remained at home attending to his own practice, why should his colleagues do his work for nothing? Why should a practitioner be paid twice over, once for the work he has done and once again for the work he has not done? That is the question which is being formulated in Southampton; but I feel that there cannot be many practitioners who are in exactly the position indicated, for if their present army pay is better than their late professional pay they cannot have had any large private practices to be nursed for them and returned to them intact, plus a large quantity of fees.

But the arrangement made at Southampton on the very first day the war was declared calls for some revision now that the war promises to be of such extent and duration. In is felt to be unfair upon medical men who remain behind that they should give their services gratuitously and to at unlimited extent for an unlimited time. The income derived from this practice might at least be shared with the absent practitioner, a proceeding which, I believe, is being followed in some districts.

If at the end of the war and on his return home from the army the practitioner finds that his private practice has not fallen to pieces, but has been carefully and honourably preserved for him by his fellow practitioners, he will have much to be thankful for. If, over and above this, he also receives not the whole but a part of what he would have earned had he remained at home, he will, at any rate, feel that his colleagues have not been unmindful of his risks.

The Question of Dependents.

It must be admitted that practitioners at Southampton may be able to afford to be generous in a way that would be impossible in some districts, for they have not lost much in consequence of the war, but this does not mean to say that the war has brought no troubles in its train. To begin with, the two principal lines have left Southampton; the ships of the Royal Mail and the Castle Lines now sail from Liverpool and London. It is true that the families of the officers and crews have not all been able to leave Southampton to follow the ships. A house, held perhaps on a long lease, to say nothing of all the furniture, cannot be easily given up. Still, a considerable number of families connected with these great lines of passenger ships have left Southampton, and the practitioners miss these good paying patients. Then the difficulty in regard to the dependents of men who have enlisted is the same here as in many other places. Whatever may have been done or said elsewhere, all the practitioners I saw at Southampton declared they had only undertaken to attend gratuitously the *necessitous* dependents. But it is no easy matter to ascertain who are necessitous, and the action of the Soldiers' and Sailors' Society has added to the confusion. This society gives prescription books to members of soldiers' or sailors' families. The patient's name is put on the top of the book, and it is supposed to serve as an introduction to a medical practitioner. At Southampton some prescription books were given to people even before they were ill. Kindly ladies visiting the families of soldiers, and hearing someone say they were not quite well, would offer prescription books, and perhaps recommend their own private doctor. They did not at all realise that they were playing the part of Lady Bountiful on the cheap. Those who thus received prescription books often thought they might as well go and get a bottle of medicine, as it would not cost anyone anything except the doctor, while it was the lady who gave the prescription book who became the object of the recipient's gratitude.

The Public Medical Service.

As the dependents on soldiers are, in many cases, better off than they have ever been before, the doctors now make inquiries before giving gratuitous advice; and when they find that the patients are not in a necessitous position they are advised to join the Southampton Public Medical Service. This is the modern expression of the old Southampton Provident Medical Association which was organised by the Southampton Medical Union to fight the Friendly Societies and the speculative medical aid insurance companies. Joining this body, the former club doctors established a wage-limit and raised the subscription from 1*d.* to 1½*d.* per week. As a consequence, they lost a third of their members, but, receiving a third more pay, and were none the poorer, though they had much less work to do. Now there have been much greater alterations. The wage-limit has been altered to £3 a week, thus keeping in line with the Insurance Act, while the subscription for adults is 2½*d.* a week and for children 1½*d.* If there are more than four children the others are attended free of any charge. The members of this service can select any practitioner in the town whether he is on the panel or not, for the entire profession accepts these terms of contract practice. These are the conditions on which a great number of dependents on soldiers or sailors are now being treated. The war has thus caused no decrease in membership. During the course of last year no less than 1100 new subscribers were enrolled, and the membership of the Southampton Public Medical Service now amounts to 8819.

War Service Rendered by Civilian Doctors.

When war was declared a large number of the officers of the Royal Army Medical Corps went with the Expeditionary Force to the continent. Thereupon the practitioners at Southampton were invited to volunteer for military service and many responded. One practitioner at Shirley went, but he had four or five colleagues living around his house to look after his practice during his absence. Another sold his practice altogether, and a third has two partners to look after his interests while he is abroad. Thus it will be seen that the work to be done near the fighting-line has not disturbed, to any serious extent, medical practice at Southampton. Of greater importance is the work that has to be done at home. Netley Hospital was denuded just as the wounded were beginning to come over from the continent. Consequently about ten Southampton practitioners and consultants went on duty at Netley for a short time. As more surgeons were enrolled, notably from London hospitals, to join the army some of them were sent down to Netley and the civilian doctors returned to their ordinary practice. But the army surgeons at Netley are not likely to remain there long. They will follow the new armies to the front, and the civilian doctors of Southampton may once again be called upon to attend the wounded at Netley. Then there are many more wounded expected, and additional hospitals are being prepared to receive them. New huts are being put up at Netley, and the large buildings recently constructed for the extension of University College at Highfield have been taken over and converted into a hospital. The new blocks of the Shirley Warren workhouse infirmary have been surrendered by the guardians for the care of the Belgian wounded, so there will be much work to be done for the war without leaving Southampton. It should also be borne in mind that extraordinary precautions must be taken to prevent Southampton becoming the port of entry of infections, especially of exotic diseases. There is plague in India and Egypt, while cholera has already spread to the Austrian army. Therefore it is satisfactory to know that a large military isolation hospital is in course of construction at Southampton.

The stress caused by the war has so far fallen lightly on the members of the profession practising at Southampton. But the time is probably very close at hand when much more work and greater responsibility will be thrown upon them, while their numbers may be reduced by further departures for the front.

UNIVERSITY COLLEGE HOSPITAL.—The annual general meeting of the corporation of University College Hospital, Gower-street, W.C., was held on March 25th, Captain the Hon. E. S. Dawson being in the chair. The chairman said that the past year had been a most eventful one all over the country in all matters connected with hospitals. In their hospital they had continued and extended their work. The number of in- and out-patients both showed small increases, yet, notwithstanding the general rise in prices and cost of living, there had been a slight decrease in the average cost of patients. To afford every possible help to naval and military medical departments not only had they reserved 100 beds for treatment of cases from the front, but all members of the staff who could be spared had, in many cases at great personal sacrifice, placed their services at the disposal of the Government. In addition many students, and no fewer than 60 members past and present of the nursing staff, had also proceeded to the front. The incorporation of the National Dental Hospital as a dental department of the hospital, the chairman continued, had been one of the notable events of the year, and this department has rendered valuable service by the treatment, free of charge, of no less than 2451 recruits for the new army. All departments of the hospital continued in a high state of efficiency, and financially, by the exercise of all possible economies, the results of the year had been slightly more favourable than they had expected. The Duke of Bedford was elected president of the corporation.

Public Health.

REPORT FOR 1913 OF THE MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER OF THE ADMINISTRATIVE COUNTY OF LONDON.[1]

Dr. W. H. Hamer's annual report for 1913 has recently been presented to the London County Council. It constitutes Vol. III. of the Council's general report, and has been issued under a separate cover for the convenience of readers. In the medical officer's report for 1912[2] announcement was made of a complete reorganisation of the Central Health Department consequent on the decision of the Council to coördinate, under Dr. Hamer's direction, the whole of the medical work respecting public health and education for which that authority is responsible. In that report, the first in his dual capacity, details were given of the administrative changes required by the Council's decision. A second year's experience under the new régime appears to justify the action taken. It further teaches that in similar cases wherever responsibility can be centred in one office more satisfactory results may be looked for than in those cases where responsibility is shared by separate departments.

The present report, like its predecessor, covers a very wide range, and for this reason we can only touch on a few of the more important topics therein discussed in detail. It bears abundant evidence of Dr. Hamer's assiduity in dealing with the many complex problems that require his personal attention. Having ourselves profited by its study, we earnestly commend this volume to the consideration of all those who are solicitous for the welfare of London's vast population. Equally evident is the despatch with which the extensive administrative changes in the health department have been accomplished by the central staff, and this at a time of extraordinary pressure on their resources.

Part I. of this report, which relates to public health generally, is dealt with in the present article. Administrative action for education purposes, as recorded in Part II., will form the subject of a future notice. In our remarks on the several matters discussed the order adopted in the original will be followed.

PART I.—(A) VITAL STATISTICS.

The loss of population by outward migration in recent years was alluded to in the annual report for 1912, and the subject is now more fully discussed. The population of London is still estimated to have exceeded 4½ millions in the middle of 1913. The composition of the population differs materially in the two areas into which the county is divided by the Thames. By the year 1891 London north of the river had been so greatly over-built that the rapidly increasing population could not be housed within the county boundary. Consequently, there has been since that date a constant overflow of the London population into the adjoining counties of Essex and Middlesex. But, in 1891, so much of the area south of the river remained undeveloped that the outward extension has not overflowed the county boundary to the same extent. The modifying effect of these variations on the age and sex constitution of the aggregate London population is explained in the text.

London Birth-rate.

In the year under notice the ratio of live births to population was the same as in 1912—namely, 24·5 per 1000—and thus, for the first time in ten years, no decline is recorded. This fact might conceivably be attributed to the effect of the National Insurance Act; but it is noteworthy that a similar pause in the fall of the birth-rate is reported in Paris, Amsterdam, and Stockholm among foreign capitals. In England and Wales as a whole the birth-rate increased from 23·8 in 1912 to 23·9 in 1913. In the metropolitan sanitary areas the usual wide differences persist, the proportions ranging from 9·2 and 14·2 respectively in the cities of London and Westminster to 31·0 in the borough of Bermondsey and 32·0 in Poplar. Of the success achieved under the Births Notification Act details are given in a table which shows marked differences in the extent to which its provisions have been locally complied with. For example, whilst in Wandsworth the registered births exceeded by more than 2000 the births notified under the Act, the latter, on the contrary, were actually the more numerous in Finsbury and in some other districts.

[2] A notice of this report appeared in THE LANCET of April 18th, 1914, p. 1137.

Comparative Mortality.

The London death-rate in 1913 was equal to 14·2 per 1000 living, which is slightly above the rates of 1910 and 1912, but with these exceptions is lower than any previously recorded rate. For many years past the London health reports have contained diagrams in which the successive death-rates are represented in relation to the mean of the rates obtaining in a long series of years. In the present diagram the decline in mortality, which with few interruptions has been practically continuous since 1880, is represented by light shading. It is possible that to the casual reader the graphic method may appeal more forcibly than does the usual array of figures, inasmuch as it shows at a glance the measure of the life saving accomplished in recent years. As in previous reports, endeavour has been made to obtain by appeal to life-tables an approximate estimate of the effects on the London community of fluctuations in mortality, the method employed having been first introduced by Dr. John F. W. Tatham in his reports on the health of Manchester. The advantages of this method, together with the formulæ employed, are detailed in the London Health Report for 1901. With the help of the new London life-table the number of deaths occurring in 1913 is compared with the number that would have occurred had the death-rate prevailing in the preceding decennium been maintained in that year. The number of lives gained in the latter period are also shown, and the figures given express that gain in terms of "life capital," this being obtained by applying the mean future lifetime figures to the lives gained at each age-group. From the appended table we learn that in the year 1913, as compared with 1901–10 there has accrued a saving of 7847 lives, representing a gain to the London community of 387,897 years of "life capital."

Loss of Life in Infancy.

In the year under review the deaths below the age of one year were in the proportion of 105 per 1000 births, against 91 per 1000 in 1912, the deaths in both years showing an encouraging decline from the high rates prevailing in the opening quinquennium of the century. The report indicates that among metropolitan boroughs Shoreditch fared worst and Hampstead best in respect of infant mortality both in 1913 and in the preceding five years. Systematic examination continues to be made of the infant mortality tables prepared by district health officers in accordance with instructions from the Local Government Board. With the aid of returns derived from the improved tables first issued in 1905 comparison is now instituted between the mortality in 1913 and that of the seven antecedent years. With respect to the diseases responsible for infant fatality we note that pneumonia is the only definite heading under which excessive loss of life is recorded in 1913. With the object of illustrating the influence of social condition on infant well-being tables have been prepared in which the varying death-rates in groups of districts are contrasted. And here it must be explained that the standard adopted for determining the social condition of a district is the percentage of all children between the ages of 5 and 14 years scheduled by the Council for education purposes in the period 1905–07. The question of whether or not a child is to be scheduled depends upon circumstances which collectively form a measure of social condition. The county has been divided into five groups representing different grades of social condition—the most favoured group consists of boroughs in which less than 82 per cent. of the children were scheduled; the least favoured group, where the proportion exceeded 97 per cent. From tables relating to the period 1905–12 it appears that in each successive trimester of the first year of life the difference in the mortality obtaining in the several groups of districts becomes generally more pronounced. As an extreme instance, in 1913 it may be noted that if among infants aged 3–6 months the mortality in the most favoured districts is represented by 100 it will be equal to 202 in the least favoured districts.

Principal Epidemic Diseases.

The experience of London in 1913 under the Infectious Diseases Notification Act shows an increase in the number of cases of scarlet fever, diphtheria, and erysipelas, and a decrease in the number of cases of small-pox, typhoid fever, and puerperal fever.

Scarlet fever.—The notified cases of this disease exceeded by 6240 the number in the previous year, but the type of disease continues to be mild and the mortality rate is comparatively low. High incidence of attack is not confined to London, but has occurred in several other large towns. Mr. G. Millson, of Southwark, states that increased scarlet fever prevalence has generally been observed there in five-year cycles. The outbreak of 1913, however, followed on a quiescent period of seven years' duration. He finds that the average age of the patients has not increased in Southwark, and concludes that if a child escapes scarlet fever up to the age of five years he stands a fair chance of escaping it altogether. This question would repay attentive study.

Enteric fever.—The low level of enteric or typhoid fever prevalence maintained for several years has again been observed in 1913. For in that year, as also in 1909 and 1912, there was practically no autumnal increase. Reasons exist for the belief that the great majority of London attacks in these years were due to causes other than the drinking of polluted water. In this connexion the recent important researches of Dr. A. C. Houston, water examiner to the London Water Board, are discussed in considerable detail. In his report for 1913 this observer throws additional side-lights on the etiology of typhoid fever. He has lately repeated earlier attempts to isolate organisms resembling the typhoid bacillus in raw Thames water. In this attempt he has been successful in two instances only. But on both these occasions he has demonstrated by rigorous tests the presence of microbes indistinguishable from the typhoid bacillus. Inasmuch, however, as this result has accrued from the examination of not more than two or three dozen gallons of raw water, it is clear that the entire London water-supply may at times contain large numbers of such bacilli. And yet no one ventures to suggest that drinking water seriously contributes to the amount of typhoid fever in London. The principle is established that failure to demonstrate the presence of the bacillus in a particular specimen of water does not prove that the bacillus is not there. Moreover, experience teaches that, in any event, the presence of the bacillus typhosus is by no means the same thing as its potential infectivity. Dr. Houston discusses two problems: "Whether typhoid bacilli reach the consumer singly or in clumps; and whether one or a number are necessary to start the infective process"—problems which, as he says, are of "extreme interest to epidemiologists." He adds that "if a single typhoid bacillus ingested with a draught of water can conceivably infect with typhoid fever a susceptible individual, this would be a serious matter: but if, as seems more probable, a number are always or usually required to start the infective process, and they are present as individuals and not as 'clumps,' and are equally distributed through filtered water, infection might seldom, if ever, take place." Recent study of the bacteriology of water would appear to indicate that the observer who maintains that the bacillus typhosus is the causal organism of typhoid fever will be obliged to assume either (*a*) that something must be conjoined with the bacillus if it is to be "effective," or (*b*) that no final deduction can be drawn from the presence of single bacilli, and that insistence must be laid on the question of dosage.

Tuberculosis.

It is shown by a diagram that in both sexes a marked decline has occurred in London mortality from tuberculous phthisis; that males are more liable than females to fatal attack; and that until recent years the decline has been most conspicuous among females. A table is given showing phthisis mortality in 1913 in groups of London districts arranged in order of "social condition." If, for example, the London phthisis rate be taken at 1000, the rate in the more favoured districts will be represented by 547 and in the less favoured districts by 1389. A point of considerable importance, showing the influence of the population movement on the phthisis death-rate, is this—that in areas of better social class a greater number of London residents of the better class, than of the poorer classes, die away from Greater London. In his remarks on local variations of tuberculous mortality Dr. Hamer compares its age incidence in this country with that of Ireland, Prussia, and the United States of America. Illustrative curves have been prepared which show a

* Including membranous croup.

† The death-rates are corrected for variations in sex and age constitution of the populations of the several boroughs, the population of England and Wales being taken as the standard.

maximum incidence of mortality at ages 20–35 in Ireland, at 35–45 in England, and at 60–70 in Prussia, while the American curve exhibits two periods of high incidence—viz., at about the fortieth and seventieth years. These differences are discussed at some length in relation to fashion in nomenclature, to migration, and to varying degrees of urbanisation in the countries compared; and the conclusion is drawn that the very variable connotation of the expression "tuberculous" at different times and in different countries largely accounts for reported differences of age incidence. In support of this view attention is called to the fact that the American curve is suggestive of a blending of the English and Prussian curves; and the fact that a considerable proportion of America is of German origin is suggested as a partial explanation of this phenomenon.

I.—(B) ADMINISTRATION.

Tuberculosis schemes.—Under this heading Dr. Hamer gives account of the preliminary arrangements already in progress under the National Insurance Act for the treatment of tuberculosis. Briefly stated, the scheme contemplates the provision and maintenance of dispensaries by the borough and city councils, aided by grants from the County Council. The complete scheme for coördinating the work of the various agencies for the treatment of tuberculosis was only in draft at the end of 1913. The administrative action already taken will be summarised in the report for the ensuing year.

Health visitors.—Under the provisions of the London County Council Act of 1908 considerable progress has been made in securing a supply of suitably qualified women to give advice as to the proper nurture and management of young children. The Act makes provision for the payment of Exchequer grants in supplement of the salaries of health visitors. The Council holds that the status of health visitors should be equal to that of sanitary inspectors, and in determining the amount of subsidy they will take into account whether or not the salary proposed by the sanitary authority is commensurate with such status.

Vermin inquiry.—Increasing attention is now paid to the cleansing of verminous persons. A diagram has been prepared showing the seasonal prevalence of three kinds of vermin during the last five years. Distinct improvement has been secured.

Homeless persons.—The censuses of homeless persons taken in February and in late October show a large reduction on the numbers previously discovered. In fact, the number recorded last February was less than one-quarter of the number recorded in February, 1910, when the highest number was found.

(To be concluded.)

VITAL STATISTICS.

VITAL STATISTICS OF LONDON DURING FEBRUARY, 1915.

IN the accompanying table will be found summarised complete statistics relating to sickness and mortality in the City of London and in each of the metropolitan areas. With regard to the notified cases of infectious diseases, it appears that the number of persons reported to be suffering from one or other of the 10 diseases specified in the table was equal to an annual rate of 7·4 per 1000 of the population, estimated at 4,516,612 persons; in the three preceding months the rates were 12·5, 9·2, and 7·4 per 1000 respectively. The lowest rates in February were recorded in Paddington, Kensington, Chelsea, Stoke Newington, and Poplar; and the highest rates in Bethnal Green, Stepney, Deptford, Greenwich, and Woolwich. Seven cases of small-pox were notified during the month, of which 6 belonged to Fulham and 1 to Kensington; 5 small-pox patients remained under treatment at the end of the month in the Metropolitan Asylums Hospitals. The prevalence of scarlet fever showed no variation from that recorded in the previous month; this disease was proportionally most prevalent in Hammersmith, Fulham, Bethnal Green, Deptford, Greenwich, and Woolwich. The Metropolitan Asylums Hospitals contained 2989 scarlet fever patients at the end of the month, against 4956, 4431, and 3609 at the end of the three preceding months; the weekly admissions averaged 324, against 661, 445, and 317 in the three preceding months. Diphtheria was slightly more prevalent than it had been in January; the greatest proportional prevalence of this disease was recorded in the City of Westminster, the City of London, Bethnal Green, Stepney, Bermondsey, and Woolwich. The number of diphtheria patients under treatment in the Metropolitan Asylums Hospitals, which had been 1630, 1663, and 1621 at the end of the three preceding months, had further declined to 1562 at the end of the month; the weekly admissions averaged 172, against 247, 177, and 160 in the three preceding months. Enteric fever was much more prevalent than it had been in the preceding month; the greatest proportional prevalence of this disease was recorded in Hackney, Wandsworth, Deptford, and Woolwich. The Metropolitan Asylums Hospitals contained 64 enteric fever patients at the end of the month, against 63, 68, and 50 at the end of the three preceding months; the weekly admissions averaged 13, against 8, 10, and 6 in the three preceding months. Erysipelas was proportionally most prevalent in Paddington, Fulham, Hackney, Shoreditch, Bethnal Green, Southwark, Deptford, and Woolwich. The 23 cases of puerperal fever notified during the month included 3 in Fulham. 3 in Islington, 3 in Camberwell, 2 in St. Pancras, 2 in Bethnal Green, and 2 in Lambeth. The 65 cases of cerebro-spinal meningitis included 15 in Woolwich, 7 in Camberwell, and 4 each in Kensington, Wandsworth, and Greenwich; and the cases of poliomyelitis belonged respectively to Bethnal Green, Battersea, and Wandsworth.

The mortality statistics in the table relate to the deaths of persons actually belonging to the several boroughs, the deaths occurring in institutions having been distributed among the boroughs in which the deceased persons had previously resided; the death-rates from all causes are further corrected for variations in the sex and age constitution of the populations of the several boroughs. During the four weeks ending Feb. 27th the deaths of 7187 London residents were registered, equal to an annual rate of 20·7 per 1000; in the three preceding months the rates were 14·6, 16·7, and 19·6 per 1000 respectively. The death-rates during the month ranged from 15·8 in Hampstead, 16·1 in Wandsworth, 18·2 in Lewisham, 18·4 in St. Marylebone, and 19·1 in Camberwell, to 23·0 in Fulham and in Poplar, 23·2 in the City of Westminster, 23·7 in the City of London, 24·4 in Southwark, and 24·8 in Bermondsey. The 7187 deaths from all causes included 578 which were referred to the principal infectious diseases, of which 3 resulted from small-pox, 280 from measles, 36 from scarlet fever, 70 from diphtheria, 110 from whooping-cough, 16 from enteric fever, and 63 from diarrhœa and enteritis among children under 2 years of age. The lowest death-rates from these diseases in the aggregate were recorded in Chelsea, St. Marylebone, Hampstead, Finsbury, and Greenwich; and the highest rates in Paddington, Fulham, the City of London, Bethnal Green, and Bermondsey. The 3 fatal cases of small-pox all belonged to Fulham. The 280 deaths from measles were 116 in excess of the corrected average number in the corresponding period of the five preceding years; this disease was proportionally most fatal during the month in Paddington, Fulham, Stoke Newington, the City of London, Bethnal Green, Southwark, and Bermondsey. The 36 fatal cases of scarlet fever were 20 above the corrected average number, and included 5 in Fulham, 4 in Islington, 4 in Stepney, 3 in the City of Westminster, 3 in Camberwell, and 3 in Lewisham. The 70 deaths from diphtheria were 23 above the corrected average number; this disease was proportionally most fatal in Paddington, Kensington, Islington, Stepney, Battersea, and Woolwich. The 110 fatal cases of whooping-cough were 16 below the corrected average number; the highest death-rates from this disease were recorded in Paddington, Fulham, Bermondsey, Battersea, and Deptford. The 16 deaths from enteric fever were 5 in excess of the corrected average number, and included 2 each in Islington, Hackney, Wandsworth, and Camberwell. The mortality from diarrhœa and enteritis among children under 2 years of age was proportionally greatest in the City of Westminster, Finsbury, Shoreditch, Bethnal Green, and Southwark. In conclusion, it may be stated that the aggregate mortality in London during the month from the principal infectious diseases, excluding diarrhœa, was 41·5 per cent. above the average.

THE SERVICES.

ROYAL ARMY MEDICAL CORPS.

To be Temporary Majors:—Dated March 8th: James Arthur Devine, D.S.O. Dated March 9th: William Thomas Prout, C.M.G.

The undermentioned Temporary Lieutenants to be Temporary Captains:—Dated March 25th: Charles S. Cato, late Captain, R.A.M.C., and Walter P. Yetts.

The undermentioned to be Temporary Captains:—Dated March 1st: Charles Edward Walker. Dated March 10th: Robert Fielding-Ould.

The undermentioned to be temporary Lieutenants:—Dated Feb. 28th: Arthur Wellington Matthew. Dated March 3rd: George Joseph Adams. Dated March 7th: Frederic Percy Joscelyne. Dated March 8th: George Stanley Deane, Henry Hawes Elliot, Roy Henry Rollinson-Whitaker, Alan Filmer Rook, John Sullivan, Harold Saunderson Sugars, Francis Gordon Bell, Frederick Orlando Clarke, James Keenan, Sydney Granville Tibbles, John Henry Tomlinson, Robert Lacy Kitching, Alexander Stanger Seabrooke, John Thomas Heffernan, Horace Fitzgerald Blood, and Eric Morse Townsend. Dated March 9th: Arthur Bloom and Hubert Lewis Clifford Noel. Dated March 10th: Oswald Herbert Edwards, Francis Irvine, Walter Smithies, Henry Harvard Davis, Walter Charles Campbell Kirkwood, Charles Ernest Sundell, John Dugald MacEwen, John Rodney Slack, Alfred Wallace Harvey, Timothy Sheehan, Alan Wiley, Francis Swanson Hawks, James Anderson Hutchinson, John Helby Wilkinson, Frederick Henry Rudge, Norman Gerald Horner. Dated March 11th: Douglas Compton Taylor.

SPECIAL RESERVE OF OFFICERS.

Supplementary to Regular Units or Corps: Royal Army Medical Corps.—Lieutenant Owen G. Parry-Jones is confirmed in his rank.

ROYAL NAVAL VOLUNTEER RESERVE.

The following appointments have been notified:—Surgeon Probationers: G. E. Mullins to the *Ruby*, G. B. Lowe to the *Defender*, W. F. R. Castle to the *Panther*, T. C. Wakefield to the *Owl*, J. T. Wylie to the *Shark*, F. A. V. Denning to the *Garland*, A. McA. Scott to the *Lennox*, and C. Suffern to the *Contest*.

TERRITORIAL FORCE.

Army Medical Services.

The appointment of Lieutenant-Colonel Henry G. Falkner as Assistant Director of Medical Services, with the temporary rank of Colonel, bears date Feb. 3rd.

Royal Army Medical Corps.

South Wales Mounted Brigade Field Ambulance: Major James MacK. Harrison to be Lieutenant-Colonel. Lieutenant Josiah Browne to be Captain (temporary).

3rd East Anglian Field Ambulance: Captain John R. Pooler to be Major (temporary).

3rd London (City of London) Field Ambulance: Alfred Norman George Jeans to be Lieutenant.

1st North North Midland Field Ambulance: Frank Pearce Sturm to be Lieutenant.

3rd Southern General Hospital: Captain Robert L. Gamlen resigns his commission on account of ill-health.

3rd Home Counties Field Ambulance: William Cummings to be Lieutenant.

3rd London General Hospital: Captain Sidney M. Smith is seconded.

1st London Casualty Clearing Station: Alexander Urquhart to be Lieutenant.

South Midland Casualty Clearing Station: Alexander Watkin Nuthall (late Captain, 5th Battalion, Royal Warwickshire Regiment) to be Captain.

2nd South Midland Mounted Brigade Field Ambulance: Captain Henry G. Magrath to be Major (temporary).

2nd East Anglian Field Ambulance: Captain Alister C. Young is seconded.

1st Home Counties Field Ambulance: Francis Seymour Jackson to be Lieutenant.

4th London Field Ambulance: Transport Officer and Honorary Captain Alfred J. Messent resigns his commission.

2nd Eastern General Hospital: Cyril Casson Messiter to be Lieutenant.

Attached to Units other than Medical Units.—Lieutenant Alfred J. Gibson to be Captain. To be Lieutenants: Lieutenant Lionel G. Pearson (from the 4th London Field Ambulance), Lorton Alexander Wilson, and Frank Jeffree.

SOCIETY OF MEDICAL OFFICERS OF HEALTH: SCHOOL MEDICAL SERVICE GROUP.—A meeting of the group will be held on Saturday, April 10th, at 3.30 P.M., at the society's offices, 1, Upper Montague-street, Russell-square, London, W.C. The annual meeting, postponed on account of the war, will be held at 3.30 P.M., and the general meeting immediately after tea at 4 P.M. Several items of very considerable importance to officers in the service, brought up by members or referred to the group by other official bodies, will be considered. Communications should be made to the honorary secretary of the group, Dr. A. Ashkenny, 2, London-road, Basingstoke.

Correspondence.

"Audi alteram partem."

THE WAR AND SYPHILIS.

To the Editor of THE LANCET.

SIR,—One of the results of the war which is already making itself felt is the difficulty of obtaining salvarsan or neosalvarsan, and the small stock of these preparations in this country must very shortly be exhausted. At the Lock Hospital in Dean-street, W., the demand for injections of these substances has recently been considerable, and is now far in excess of the supply which can be obtained by that institution. The average number of injections given weekly has up to recently been about 50, whereas it is now reduced to half that number, and in some instances one full dose has been divided between two cases. Consequently the institution has recently been compelled to have recourse to some of the substitutes for salvarsan, and though the results have been fairly satisfactory I am bound to say that they do not compare favourably with those obtained by the original preparations of Ehrlich. In proof of this I will mention two instances which have recently come under my observation.

CASE 1.—A patient with a secondary syphilide, who had been treated with weekly injections of "grey oil" from Oct. 31st to Dec. 12th, was found to have such symptoms of mercurialism as to render any further treatment with that drug inadvisable. Accordingly, on Jan. 2nd he was given an injection of novarsenobenzol "Billon," a French preparation which is said to be identical with neosalvarsan, and is recommended for its innocuousness. The injection was followed by only a slight immediate reaction, but at his next visit to the hospital on Jan. 9th the patient was found to be suffering from an acute dermatitis of the shoulders and hands, which in the following week was so severe as to necessitate his admission into the wards of the hospital. The dermatitis was then generalised and universal; the mucous membranes of the nose, mouth, and conjunctiva were intensely inflamed, his feet were œdematous, but there was no irritation of the intestinal tract, and the urine was normal. The dermatitis was followed by most extensive desquamation, so much so that large flakes of epidermis could be removed from the sheets of his bed literally in handfuls. He suffered from a severe purulent conjunctivitis and intense photophobia, his eyelashes were almost completely shed, as was also the hair at the back of his head. At the present time, 12 weeks after the injection, there remains an extensive xeroderma and erythema of the skin, with pustular dermatitis of the lips and hands. His condition, which at one time gave rise to the gravest anxiety, is now improving, and the prospects of his ultimate recovery are favourable.

CASE 2.—A patient suffering from secondary syphilis was admitted into the hospital on March 9th and given an injection of "kharsivan," a preparation of Messrs. Burroughs, Wellcome and Co., which is said to be identical with salvarsan; this was followed by no reaction, and he was given a second injection on March 17th. On March 19th the patient experienced severe aching pains all over the body; conjunctivitis and œdema of the eyelids and lips; diffuse and universal desquamative dermatitis, and biliuria. These symptoms are now subsiding.

My experience of these two cases leads me to think that the substitutes for salvarsan differ in their effects so far from the original preparations as to necessitate the greatest care in their employment. The two cases I have alluded to were such perfectly healthy subjects that no ill-effects could possibly have been anticipated from salvarsan treatment. In the course of an experience of this treatment extending over five years, I have never met with any cases which were followed by such intense symptoms of arsenical poisoning, and the only conclusion I can arrive at is that, though chemically the substitutes for salvarsan may be identical with the original preparations, from the clinical point of view they differ in a remarkable manner. Not only is their toxic effect, *qua* arsenic, much more intense, but their local effect on the veins is more irritating, as was manifested by several cases of thrombosis of the injected vessel following on the use of kharsivan, even when diluted with 200 c.c. of distilled water.

It is impossible to estimate the duration of the present war, but when it does come to a conclusion there will inevitably ensue a considerable increase in the incidence of venereal diseases, and in my opinion some measures should now be organised to ensure that adequate provision is made for their treatment. I am given to understand that Messrs. Burroughs, Wellcome and Co. at the present moment are experiencing some difficulty in meeting the demand for kharsivan, and if there is any great increase in the prevalence of syphilis a considerable proportion of the sufferers will be unable to obtain what is now universally acknowledged to be the best treatment for that disease—viz., salvarsan, or, failing that, one of its substitutes. Though all departments of the Government must now be working at high pressure, I venture to think that the inevitable increase in venereal diseases at the termination of the war is a subject worthy of the attention of those to whom the health of the nation is entrusted.

I am, Sir, yours faithfully,
J. ERNEST LANE, F.R.C.S. Eng.,
Surgeon to the London Lock Hospital.
Queen Anne-street, W., March 28th, 1915.

SHOULD MEN WORK SIX DAYS OR SEVEN?

To the Editor of THE LANCET.

SIR,—At the present time, when there is urgent necessity that munitions of war should be turned out with the greatest possible rapidity, it is very important that men engaged in their manufacture should be able to do the maximum amount of work with the minimum of harm to themselves. In relation to this question I think that an experiment made many years ago by my friend, the late Lindsay Russell, Surveyor General of Canada, is of great interest. Along with Professor Pearce, who represented the United States, he surveyed the boundary line between the United States and Canada so exactly that I believe its accuracy has never been called in question. On this expedition, or some of his other surveying journeys, he and his men had to pass over great spaces where there was neither game nor fishing, and were therefore obliged to take their provisions with them. The forts at which these could be replenished were generally placed about 40 days' march from each other, and as the surveying party, on account of the weight, only took sufficient provisions for the distance and no more, they were obliged to cover it in a given time for fear of starvation. On some occasions he had men and horses and on others men and dog trains. Necessity obliged him to work his men and animals as hard as they could for seven days a week and six weeks at a time. Under this strain the horses usually gave out about the twentieth day, but the men and dogs seemed to be uninjured and only to grow harder and harder. On other occasions, however, when there was no necessity for such extreme exertion he worked his men only six days a week and allowed them to rest completely on the seventh. As he was engaged in surveying operations he knew exactly how many miles his party had travelled in a day; he knew how many pounds weight each man carried, and was thus able to calculate exactly in foot-pounds the amount of every man's daily work. On reckoning it up he found, to his astonishment, that the number of foot-pounds done by the men working six days a week was almost the same as when they worked seven days a week. Although the men were able to work seven days a week to their utmost capacity all day in the open air, and sleeping in the open air all night for seven days a week without harm, it is unlikely that men working under much less favourable conditions in a factory will stand continuous work in the same way as the surveying party. In all probability if the men work at their full capacity for six days it will be better both for them and the work they turn out that they should rest on the seventh.

I am, Sir, yours faithfully,
T. LAUDER BRUNTON.
De Walden Court, W., March 29th, 1915.

LOUIS DANIEL BEAUPERTHUY AND MOSQUITO-BORNE DISEASES.

To the Editor of THE LANCET.

SIR,—Regarding the discussion between Dr. Andrew Balfour, Dr. H. Seidelin, and myself on this subject in THE LANCET of March 6th and 27th, no one wishes to deprive Beauperthuy of all the "respect and reverence" due to him as a man and a physician, but whether he was "a very great and far-seeing physician" on the strength of his hypothesis on insect-borne diseases is the question at issue. We cannot deny that he was one of those who adhered to the idea that insects are in some way connected with diseases, but, as I have said, this old hypothesis dates from the time of the Romans. My point is that his explanation of this connexion was a wrong one—that is, he thought that diseases are caused by the venom of insects and not by their capacity to carry the virus from one person to another. Moreover, from what I have seen of his writings, he seems merely to have advanced the speculations in a non-scientific manner—that is, as so many prophets do, in the form of a categorical imperative. I much prefer King's work because, in Dr. Balfour's words, "he marshalled his theories in a more logical and careful fashion." That is the whole point. One appears to me to have been a dreamer (though more careful studies of his work may correct this impression of mine), while Dr. King appears to me to have been a man of science. Moreover, King did not think that mosquitoes cause disease merely by their venom, but evidently supposed (see p. 656 of his paper) that they transmit a Bacillus malariæ—a much more rational hypothesis. Beauperthuy's hypothesis was, as I have said, contrary to reason. I am glad that Dr. Balfour agrees with what I maintained about the difference between speculation and careful research work, and that is why I mentioned the case of Beauperthuy. It has become quite a profitable art nowadays to confuse the two, though anyone can indulge in unlimited armchair speculation, while research means much toil.

Whether Beauperthuy's "zancudo bobo" was really the Stegomyia fasciata is another question, and I hope that Dr. Balfour will let us know what he thinks on this point when he has read the original papers. I wish that someone could find the papers on the mosquito theory: (*a*) by John Crawford, called Mosquital Origin of Malarial Disease, *Baltimore Observer*, 1807; and (*b*) by J. C. Nott on the Origin of Yellow Fever, *New Orleans Medical and Surgical Journal*, 1848. I have not been able to obtain either of them. All these theories are of considerable psychological interest. They were all partly right and partly wrong, and the true story now known to us shows how much more clever nature is than the wisest of us.

I am, Sir, yours faithfully,
Cavendish-square, W., March 27th, 1915. RONALD ROSS.

STOMACH *V.* HEART IN RELATION TO PRÆCORDIAL PAIN AND SUDDEN DEATH.

To the Editor of THE LANCET.

SIR,—Certain persons suffer from discomfort and pain in the præcordial region when they walk, especially uphill and soon after eating, but the moment they throw off gas from their chests or stand still their discomfort vanishes. Persons thus affected are prone to sudden death. The pain and the sudden death, when it occurs, are commonly, but erroneously, ascribed to functional or organic disease of the heart. The following case is a typical example of the class:—

> The patient, aged 48 years, had always had good health except in the matter of his digestion. Sweet foods turned sour on his stomach and distended it with gas. He was a "windy" subject, but looked robust and in good flesh. A few weeks before visiting me he became conscious of a disability which seemed likely to prevent him from following his occupation, for when he walked, particularly if soon after eating, he was seized with a most disagreeable sensation in the chest, merging into pain. No evidence of cardiac disease was detected. There was no increase in the area of cardiac dulness, no abnormal cardiac sounds, dyspnœa, or œdema, no abnormality in pulse-rate or rhythm. About five weeks after this examination, after a hearty afternoon meal, the patient left the house. When about 200 yards from his own door he fell down and was picked up dead. No lesion accounting for death was found at the necropsy. All his organs were healthy. The cardiac valves were normal and the myocardium thick and free from disease. The coronary arteries were sound, save for one or two small foci of commencing ossification. Their pathological condition was such as might be expected in persons dying at the same age from indifferent complaints.[1]

The manner in which seizures affected this patient is thus described in his own words:—

> When I leave home in the morning I usually feel quite well, but after walking 100 paces or more I am conscious of an uncomfortable sensation at the stomach and a desire to expel gas from the chest. I have also a feeling as if a piece of crust had become lodged in my gullet, pain creeps up from the pit of the stomach to the chest and spreads all over it, sometimes reaching the armpits, shoulders, and back, and even extending to the neck and jaws. Water gathers in my mouth and runs out upon my chin; it is neither retched nor coughed up, but comes into my mouth on its own. My eyes fill with tears; sometimes urine dribbles away from the bladder in spite of my efforts to prevent its escape. If at this time I can break wind from the chest all this discomfort vanishes in a second. So every now and then I stop and retch and throw gas from my chest, and when all is thrown off I can walk as well and as far as I ever did before. But sometimes the gas is hard and will not come up, and then a dreadful feeling comes over me; it is as if my head swims and my chest is gripped and held tight, and all strength is going from my limbs, but even when no gas comes up, if I stop walking and remain for a few seconds standing still the seizure passes off.

When asked what distance he had walked upon any occasion just after the occurrence of seizures, the patient said:

> On Bank Holiday, soon after starting from home in the morning, I was taken with a seizure which was followed by two others, but after I had stood still for a few seconds and broken up wind I walked on without having to stop again and visited a friend living five miles away. That morning I walked ten miles, counting the journey there and back again, without being troubled with any pain whatsoever; indeed, I never felt better in all my life than during that walk.[2]

The fact that the patient walked ten miles just after three seizures indicates that exhaustion of reserve power of the function of contractibility is not the causal agency of these seizures.

From a consideration of the description of this seizure, and seizures of a similar kind which have occurred in other patients under my notice, it is to be remarked that segments of the medulla and cord, secretory glands, and parietal, visceral and cardio-arterial layers of muscle, take part in the manifestations of the seizure. Consequently symptoms constituting the syndrome are divisible into five groups: (1) The central nervous group comprises referred pain felt in the distributory areas of the brachial plexus and the second, ninth, and intermediate intercostal nerves, and algesia affecting scattered patches of the integuments and deeper structures of the thoracic wall and adjacent parts; (2) the secretory group comprises a voluminous flow of watery saliva and increased secretion of lacrymal glands with probably also increased urinary secretion; (3) the parietal muscular group comprises contractions of facial, intercostal and abdominal muscle, the latter contractions producing a sensation of pressure over the thoracic wall described by some as fixation or tightness of the chest walls; (4) the visceral muscular group comprises nausea, retchings, and eructations resulting from contractions of the gastro-œsophageal sheet and diaphragm; and (5) the cardio-arterial muscular group comprises vaso-constrictions, elevation of blood pressure, abnormal deviations in pulse-rate and disturbances of rhythm and sometimes total inhibition of cardiac function.

The seizure consists of the associated manifestations of these several groups of symptoms. The muscles and secretory glands which produce groups 2 to 5 inclusive are not in functional communication with one another except through the central nervous system. Hence the central nervous system furnishes the link that connects in a unity of expression the several activities that produce the seizure. The central nervous system must therefore be regarded as the seat of the predisposing cause, otherwise the activities producing the seizure would fail to combine in unitary expression. For if the heart be the seat of the predisposing cause, how are symptoms witnessed during seizures to be accounted for? If segmentary centres be healthy can impressions from the myocardium cause cramp in the recti abdominis muscles or agonising pain in the distributory regions of intercostal nerves? Can impressions generated in the myocardium cause nausea, overflow of saliva, retching, eructations of gas, and vomiting? Through what mechanism can impressions emanating from the myocardium cause vaso-constriction in systemic arterioles and an elevation of blood pressure? Without an appeal to a disordered central nervous system can any disease of the heart cause instant death? Even in complete heart-block the ventricle, if robust, still bears the burden of rhythm.

---

[1] At the necropsy made upon the "unknown" by John Hunter and described by Heberden the vessels were found healthy and the heart sound and vigorous.—Medical Transactions of the Royal College of Physicians.

[2] Cases in which long walks are taken after seizures are not infrequent. Dr. Mackenzie refers to cases of this kind in the Oliver-Sharpey lectures.

It may be replied that disturbance of myocardial function causes hyper-irritability at segmentary centres of the thoracic cord, and as a result of this morbid condition the symptoms indicated above appear. But apart from the fact that dendritic connexion between the myocardium proper and segments of the thoracic cord is not open to proof, this statement merely affirms that the predisposing cause of the seizure really lies in the central nervous system, and that the remote cause of the seizure is to be found in the myocardium. The hypothesis that the myocardium is the seat of the predisposing cause is therefore an absurdity. The same method of argument is applicable to all the other alternative propositions. A confirmatory symptom is present during seizures and at intervals between them—viz., patches of algesia are found in the distribution of intercostal and spinal accessory nerves. Strands of the brachial plexuses in the posterior cervical triangle and branches of the plexuses in the arms are tender upon pressure. This symptom appears in regions where pain is never felt and at seasons when the patient is at rest and when seizures are in abeyance. In a certain case examinations have been made by me on frequent occasions during an illness of three years' duration, and in no instance has this symptom been entirely absent. But algesia shifts its ground from day to day—patches appear in a zonal area, remain in evidence for a few hours, disappear and reappear. Charts showing the distribution of patches of algesia are never found alike upon two days in succession. Precisely the same characteristics are noticed even at intervals when no seizures are occurring. It is evident that it is not the seizure which makes the patch, but that neurosis of segmentary centres determines both patch and seizure. Hence we are in a position to infer that a state of neurosis at segmentary centres is the predisposing cause of seizures, and that vagal inhibition is the cause of death.

This conclusion is important because segmentary neurosis is the predisposing cause of diseases belonging to the class of the paroxysmal spasmodic disorders associated with the musculature of the alimentary canal. In members of this class seizures occur in connexion with food-taking and gastro-œsophageal hypertonus; they also occur from mental and emotional excitement and from muscular effort; in them both visceral and parietal layers of muscle are engaged in spasm. Consequently they resemble the anginal seizure in other features besides that of predisposing cause. A neurosis attended by intercostal hyperalgesia ensues when dendritic fibres belonging to the affected centre traverse pressure zones of hyperplasias, aneurysms, new growths, and pericardial and pleuritic adhesions. Hence these diseases as well as gastric disorders may be regarded as potential remote causes of anginal pains and seizures.

I am, Sir, yours faithfully,
H. WALTER VERDON.

Streatham Hill, S.W., March 19th, 1915.

INFLUENZA OR EPIDEMIC CATARRH.

To the Editor of THE LANCET.

SIR,—As a bacteriologist I often have to suffer mental pain at the misuse of the term "influenza," and therefore I should like to record my cordial agreement with the general principles laid down in your leading article on this subject in THE LANCET of March 6th, at the same time apologising for the belatedness of this letter. I must, however, say that my experience of this epidemic appears to entirely negative the doubt expressed in the article as to the existence of a definite epidemic due to Pfeiffer's bacillus. My experience was as follows: Up to Jan. 19th I had seen no cases of recently contracted influenza infections for some months, and it would appear that at that time I was not alone in that experience, for we, at St. Mary's Hospital, were a few days prior to that date asked for a culture by the Lister Institute and were not immediately able to supply it. It was, however, supplied from a culture isolated from a case of bronchial catarrh I saw on Jan. 19th. From that date to March 1st I isolated Pfeiffer's bacillus from 14 more cases, and from March 1st to date I have isolated five more strains. The cases were not hunted for; they came in the ordinary routine of practice, and vaccines were made, or will be made, in each case but one, where a lady apparently contracted the infection from her husband and his vaccine was deemed appropriate. Other two of the cases were those of husband and wife.

My general impression has been that the epidemic, though widespread, has not produced many severe cases. Moreover, I think that the organisms have been a degree more difficult to cultivate than in former epidemics. I may say that I rely only to a slight extent on the initial impression gained by the microscopical examination of a film, and indeed I find that nothing short of the employment of an agar plate, rich in fresh blood, gives one any confidence in giving an opinion. This, I imagine, is the experience of every competent bacteriologist. The recently existing epidemic was so general that I think one was quite justified in exploiting stock vaccines of Pfeiffer's bacillus for the treatment of acute catarrhs of upper respiratory passages, to discount the delay entailed in making exact diagnosis by cultural methods.

But, Sir, if THE LANCET be doubtful as to the bacterial cause of a widely spread and definite epidemic, what expectation can there be that the profession at large is in possession of approximately accurate knowledge on the subject? It would seem that there is urgent need of some kind of bulletin for issuing information as to the bacterial cause of prevailing epidemics of catarrh.

I am, Sir, yours faithfully,

Wimpole-street, W., March 23th, 1915. JOHN MATTHEWS.

CERTAIN PECULIAR CRYSTALS FOUND IN CEREBRO-SPINAL FLUID.

To the Editor of THE LANCET.

SIR,—Dr. W. W. D. Thomson has contributed an article to THE LANCET of March 27th under the above heading, and has taken considerable pains to describe and have examined by Mr. A. R. Dwerryhouse certain crystals which he found mingled with the pus in a case of septic meningitis. I am afraid he has been led astray and fallen badly into one of the numerous traps set for the pathologist. The crystals he describes have been deposited from the water in which the bottle or syringe has been boiled for purposes of sterilisation. I would suggest that Dr. Thomson verifies this by boiling some tap-water in a test-tube for a short time, let it cool, and then examine the deposit.

Some years ago these crystals gave me trouble by obscuring to a certain degree the scanty deposit of cells found in tabetic and many tuberculous cases, especially the latter. In films stained with carbol-fuchsin for tubercle bacilli the crystals retain some of the stain, and so may cause confusion. Since that time I have always used test-tubes sterilised by boiling in *distilled* water or, better, in a dry oven. Dr. Thomson does not state whether the staphylococci were numerous on the agar tube or whether they were Gram-positive. Nor does he indicate whether the colonies were white or yellow. It is a pity the streptothrix was not more fully investigated.

I am, Sir, yours faithfully,

Harley-street, W., March 28th, 1915. ERNEST H. SHAW.

A NEW TYPE OF FRACTURE OF THE ANKLE.

To the Editor of THE LANCET.

SIR,—The important injury referred to under the above heading in an annotation in your issue of March 27th was fully described by Etienne Destot in his book "Traumatismes du Pied et Rayons X," published in 1911. Dr. F. J. Cotton's advice to treat this posterior marginal fracture of the lower articular surface of the tibia by fixing the foot in the fully dorsiflexed position I can endorse from experience. I emphasised this point in an article[1] last year. When the backward displacement of the foot cannot be wholly corrected by dorsiflexing the foot under an anæsthetic, and in cases in which the proper treatment has not been carried out in time, open operation is necessary. In the *Polyclinic* of August, 1913, was recorded a case in which I fixed the tibial fragment by a Lane's plate. This fracture so often complicates Pott's fracture, bimalleolar fracture, and other common injuries at the ankle that I suspect its presence until contrary proof is afforded by good radiograms.

I am, Sir, yours faithfally,

J. JACKSON CLARKE.

Portland-place, W., March 29th, 1915.

---

[1] Open Operations in the Treatment of Fractures and Dislocations, Universal Medical Record, 1914.

NURSE-MIDWIVES IN CORNWALL.—At the annual meeting of the friends of the Cornwall County Nursing Association, held last week, it was suggested that the Local Government Board would help to establish qualified nurse-midwives in scattered country districts where there was no resident midwife, and often no doctor, and where it was impossible to provide locally sufficient funds for the maintenance of a nurse.

ROYAL GLOUCESTERSHIRE INFIRMARY. — The annual meeting of the subscribers to this institution was held on March 25th, under the presidency of Colonel Curtis Hayward. The medical report stated that during the year 1619 in-patients, including 133 soldiers, were admitted—the largest number of admissions on record. 7381 out-patients, including 786 soldiers, were treated, an increase of 300 compared with 1913. The financial statement showed an unfavourable balance of £1144 at the close of 1914.

The War.

HONOURS LIST.

Lieutenant Edmund Hume Moore, R.A.M.C., attached to the 2nd Battalion the Leicestershire Regiment, has been appointed D.S.O. for distinguished gallantry on Feb. 23rd near Richebourg L'Avoue, in going with another officer (Captain N. A. Morgan, 2nd Battalion of the same regiment, also appointed to the Order) and a stretcher-bearer to within 150 yards of the enemy to attend to a wounded soldier. The stretcher-bearer was also wounded, and both wounded men were successfully carried to the rear. On the next day Lieutenant Moore again dressed a wounded man under the direct aimed fire of the enemy and was himself wounded.—Lieutenant T. W. Clarke, R.A.M.C., has been awarded the Military Cross for conspicuous gallantry and great devotion to duty during six months. On March 5th, when the 14th Field Ambulance was destroyed by a shell, killing one officer and five men and wounding 19, Lieutenant Clarke continued to attend to the wounded though wounded himself, until he collapsed.

THE CASUALTY LIST.

Since our last issue the casualties reported in our Expeditionary Force include the names of Captain H. S. Cormack, I.M.S., Lieutenant H. M. Mackenzie, R.A.M.C., Lieutenant R. F. Wilkinson, R.A.M.C., and Lieutenant J. W. Cannon, R.A.M.C., all wounded.

Dr. J. C. Fox, a medical missionary, whose name was included in the official list of missing from the roll of the *Falaba*, is announced to have been saved.

THE INCREASED PREPARATIONS FOR THE WOUNDED.

The need for a greatly increased supply of nurses, to which we referred in these columns last week, has since been emphasised by the appeal of the Director-General of the Army Medical Service to civil hospitals with training schools. After gratefully acknowledging the great help which these hospitals have already given, Sir Alfred Keogh asked them to still further assist the country by making every effort to train for three or six months as many probationers as possible, so that they may be available for work later under supervision in military hospitals. The appeal under present circumstances is fully justified, though the scheme will undoubtedly require careful organisation in order to overcome difficulties which existing conditions present.

The London Hospital has already anticipated a brisk demand for nurses with only a short training, and the authorities at St. Bartholomew's Hospital have expressed their willingness to accept immediately pupils for a short course of practical nursing, but other training schools have not yet seen their way to adopt the course suggested at present. Lack of adequate accommodation for those who are undergoing complete training no doubt presents very real difficulties in some institutions already working at full pressure. There can be no doubt, however, as to the necessity for providing a sufficient number of trained women to look after our sick and wounded, and mutual goodwill should not find it difficult to readjust existing conditions to present needs. It is announced that candidates from hospitals of 50 beds will be accepted if suitable in other respects. Candidates between the ages of 35 and 45 who are accepted will serve for a year either at home or abroad, but for home service this age-limit will be extended, especially for the higher posts. Women outside the ranks of fully or partially trained hospital nurses will be accepted in certain hospitals as probationers for a month, and if found suitable may sign on for a year or for the duration of the war. The age-limits are from 23 to 38. It is estimated that some 3000 carefully chosen certificated women will be required.

The need for nurses has also brought home to the public the circumstance that nurses who have suffered, or may suffer, from attendance upon the sick and wounded during the war have no adequate provision made for them in return. The originating of a Fund for this purpose has occurred to Miss Swift, matron-in-chief of the joint committee of the Order of St. John of Jerusalem and the British Red Cross Society, and an appeal has been issued, accompanied by a promise of £1000 from the Red Cross Society, and of a similar sum from the Order of St. John of Jerusalem. The patrons of the Fund are Queen Mary and Queen Alexandra, and the committee includes many who have a practical knowledge of nursing. The address of the Fund is 15, Buckingham-street, Strand London, W.C., and cheques may be made payable to Sir Everard Hambro, the chairman and treasurer, and crossed the Bank of England, or they may be sent to the Bank of England to be placed to the credit of the Fund. Nurses on the staffs of the Navy and Army and in the Reserve and Territorial Forces are already provided for, but no provision has hitherto been made for civil nurses, while the risks which they run of being incapacitated from work are extremely great, for many are working in hospitals where, in addition to the dangers from shot and shell, the perhaps greater dangers resulting from insanitary environment are added. We are glad to learn that the public is responding well to the call for help in this direction.

No special generosity to nurses at the present moment must, however, be allowed to interfere with a careful investigation of the question of their payment. We feel sure that under the Royal patronage which it commands, and with the able judgment of a strong committee, the new Fund will receive all the support which it requires to carry out its beneficent work; but it is necessary, also, that we should face the whole question of the pay of nurses fairly and squarely.

KITCHENER'S INDIAN HOSPITAL.—There has been established at the old Brighton Poor-law Institution a large Indian general hospital, known as Kitchener's Indian Hospital. This is in addition to the Indian hospitals at the Dome and York-place School. The hospital is situated on an open elevated spot in the town, adjoining the racecourse and close to the open downs. The staff of the hospital is mainly derived from members of the Indian Medical Service, with a number of native Indian medical officers assisting. The officer in command is Colonel Sir Bruce Seton, of Simla, honorary surgeon to the Viceroy. The medical and surgical wards, which contain altogether about 1700 beds, vary in size, the smallest holding eight, the largest about 50. They are well arranged and comfortably appointed. There are separate huts for infectious cases and a special ward for all tuberculous patients, where open-air treatment is available. There is also a ward for lunatics, which is fitted out with all modern improvements, including padded cells, wire-gauze windows, and protected radiators and electric lights. There are three operating theatres, with sterilising rooms adjacent, but up to the present not many operations have been performed. Now that many cases of bullet wound are being admitted, the number will rapidly increase.

The electrotherapeutic department is fitted out with every requirement for this branch of medicine. There are 12 Dowsing radiant-heat beds and smaller apparatus for the treatment of limbs and joints in this way. Many cases of trench rheumatism and frost-bite have been thus treated with very satisfactory results. There are also a universal machine for galvanism, faradism, sinusoidal current, light, cautery, and vibratory massage, a high-frequency apparatus, and a Schnee's four-cell bath for hands and feet, which can be used for galvanism, faradism, and sinusoidal currents. The pathological department has all the modern apparatus required for the pathological examination of urine, blood, sputum, and cerebro-spinal fluid, the preparation of vaccines and sera, and the various pathological tests, such as Wassermann's and Widal's, an autoclave, electric centrifuge, hot-air steriliser, and incubators. The pathological work of all the Indian hospitals in the town is carried out here. The X ray department is similarly equipped with all the latest instruments necessary for diagnosis and treatment. As a matter of routine every bullet wound is examined here, and when one remembers that on one day 500 cases of this nature were admitted, it will be realised how busy the officers of this department are kept. The nursing is all done by men, either Royal Army Medical Corps or native Indian orderlies. As all these were untrained on enlistment it is as gratifying as it is surprising that the nursing has so far, on the whole, been considered satisfactory both by the medical staff and the patients. When the more serious cases are admitted, such as enteric fever, pneumonia, compound fracture of the lower extremity, gunshot wounds of the spine, abdominal operations, and such-like, it will then probably be found absolutely necessary to add some highly trained and fully qualified nurses to the hospital equipment. At present no women are employed in the hospital in any capacity whatever.

There is everything within the hospital to make it self-contained—a steam laundry, a barber's shop, a dry canteen, three linen disinfectors, a linen store, a pack store, even cells for prisoners, a rifle-range, a gymnasium, recreation rooms for the men, a hut village for the staff capable of holding 400, special quarters for wounded native officers, with their own nursing staff and cooks. In fact, little if anything has been omitted which could possibly have been included in the equipment of the institution. All records, whether of admissions, of deaths, of special treatments, such as X ray examinations, pathological treatment, and so forth, are kept on the card-index system, and thus the record of all patients can be traced with the minimum of trouble. All the sanitary arrangements are made to comply as far as practicable with native customs, and the same applies to the burial of the dead. So far there have been very few deaths, only three in the total admissions, which number 1200. The diet of the patients is naturally quite different from that of our own men. The ordinary diet consists of 8 ounces of meat, with *atta* or rice, *dhall* or peas, butter or *ghee*, potatoes, fresh vegetables, fresh fruit, onions, tea, *gur* or sugar, chillies, turmeric, garlic, salt, and milk. There are three meals—breakfast, mid-day meal, and supper.

The convalescent patients are kept fit by light duties and daily route marches, and every care is taken of them whilst out for walks or going to places of entertainment. They always go under escort. When it is known that races so different as Sikhs, Gurkhas, Pathans, Punjabis, Dograhs, Garhwalis, Afridis, Baluchis, and Mahrattas are among the admissions, it will be seen that a good deal of management is required to make all the arrangements satisfactory. Colonel Sir Bruce Seton is to be heartily congratulated on the success that has attended his efforts to convert the Poor-law Institution into one of the most up-to-date and best equipped military hospitals in the kingdom.

VOLUNTARY AID DETACHMENTS, BRITISH RED CROSS.—We are asked to state that the Voluntary Aid Detachments Selection Board of the British Red Cross Society has moved from 83, Pall Mall, to Devonshire House, Piccadilly. The hours for interviewing candidates are 10 to 1 every day, and 2.30 to 4.30, with the exception of Wednesdays and Saturdays.

The Medical Plight of Serbia.—The plight of Serbia in the grip of typhus fever is serious, and unless the other nations come to the aid of this gallant little State disease will finish off what the more immediate brutalities of war have spared. We have heard through the press what Sir Thomas Lipton saw there, and on March 22nd a large meeting was held at the Mansion House in support of the Serbian Relief Fund, whose headquarters are at 55, Berners-street, W. Various units have been at work in Serbia. Lady Wimborne sent out 4 medical men and 42 orderlies and nurses on behalf of the Serbian Relief Fund, while Lady Paget, who is in charge of another unit at Uskub, is herself down with typhus fever there. Miss Hankin Hardy is in charge of a hospital at Kragnevatz, where she has 600 patients with only one Serbian lady doctor, no nurses, and four Austrian prisoners as orderlies. The death from typhus fever of Dr. Elizabeth McB. Ross, of the Scottish Hospital at this place, was recorded in our issue of March 20th. The American Red Cross has a hospital at Belgrade under Dr. Ryan and one at Gevgelija, the chief of which, Dr. Donnelly, died there from typhus fever, with two of the nurses. About 100 French doctors are said to be *en route* to Serbia to assist in stamping out typhus, and we learn that 25 officers of the Royal Army Medical Corps, under Colonel Hunter, have recently arrived in Serbia for duty. The hospital accommodation, where it exists, is of the most meagre and is filled to overflowing, and there appears to be none at all save in the most important towns, so that the patients lie out, often untended, in the streets. Stores also are deficient, not only drugs and dressings, but bedding, clothing, and all the necessary equipment for satisfactory hospital work. Typhus fever, owing to poverty, the impossibility of isolation, and overcrowding, is occurring in tens of thousands of cases, and it is to be feared, unless adequate preventive measures can be initiated, that with the advent of the warm weather cholera may succeed it. Not only on the score of humanity and present international ties through a common cause should every assistance in personnel and material be given to our courageous little ally, but even on the ground of self-interest, having in view the method by which migration of troops spreads disease, it is highly important that we should come to their aid.

Among the passengers on the Admiralty ship *Saidish*, which leaves immediately for Salonica, will be the advance guard of a hospital unit, sent by the Wounded Allies Relief Committee, Sardinia House, Kingsway, W.C. This advance guard will consist of two doctors and two nurses, armed with medical stores. Both the doctors are Belgians who have seen service in the war, while one of the nurses is a Russian lady, who is acquainted with the Serbian language and who has been doing valuable work at the Ambulance Jeanne D'Arc at Calais. The work of these forerunners will be to prepare the building provided by the Serbian Government, so that on the arrival of the rest of the unit work will begin at once.

The committee of the Wounded Allies Relief Fund asks for subscriptions towards this work, and any such will be welcomed by the honorary treasurers, the Hon. Mrs. Fredk. Guest, 26, Park-lane, W., and Mr. T. O. Roberts, manager, London County and Westminster Bank, 217, Strand, W.C. The Fund will shortly open a temporary resting-place for homeless Belgian soldiers in premises which have been lent them for the purpose.

Vacancies for Medical Officers.—We are asked to state that a vacancy exists for a Surgeon Lieutenant (Attached) to Kent (F.) Royal Engineers, to replace medical officer detailed to take charge of an ambulance train (railway). The appointment could be for the period of the war or otherwise. The headquarters, the station of the surgeon, are near Chatham. Correspondence should be addressed to Major H. F. Stephens, O.C., K.(F.)R.E. Head Quarters, Pier-road, Gillingham.—There are vacancies for two medical officers in the 2nd Line Welsh Border Mounted Brigade Field Ambulance. Pay and allowances as in the Regular Army, also a grant for outfit and camp kit. Further particulars can be obtained on application to Major D. C. Leyland Orton, R.A.M.C (officer commanding), Thomas-street, Chester.—Two medical officers are required at once for the 1st North Midland Field Ambulance. Applications should be sent to the Officer Commanding, R.A.M.C. Depôt, 91, Siddals-road, Derby.

Russian Medical Students Specialising for the War.—A correspondent informs us that, in view of the urgency for increasing the medical service, both for the army and for civil life, it is found to be necessary to interrupt the regular studies of medical students and in all universities to give them special courses in military field surgery and attention to the wounded; in the knowledge of internal complaints common in war; in military field hygiene; and in dealing with epidemics. These studies are to continue till May. The regulation examinations will be delayed so that the students may give undivided attention to these special studies.

The Duchess of Connaught Hospital.—Among the many benefits to the wounded, for which this country is partly indebted to the Canadian Red Cross Society, is the hospital at Cliveden, Taplow, constructed in the covered tennis-courts at Cliveden generously given by Major and Mrs. Waldorf Astor. Early in the autumn the owners of Cliveden placed these courts at the disposal of the Canadian Red Cross Society, who have now equipped the hospital, which has 100 beds, and have supplied a staff of medical officers, nurses, and orderlies, undertaking at the same time to defray the working expenses. All the beds are now occupied by wounded British and Canadian troops. The staff consists of Lieutenant-Colonel Charles Gorrell, of the Canadian Army Medical Corps, the officer commanding, with 10 other medical officers and 20 nurses, besides orderlies, of whom 32 are medical men and 1 a dentist. The situation of the building on the heights above the Cliveden woods is admirably airy, and, the courts being covered in by a glass roof, the whole building is very light. The hospital is fully equipped with an X ray room, laboratory, and offices, and it is intended by the Canadian Red Cross Society to make provision for as many as 500 beds, enlarging the staff proportionally.

Queen Alexandra's Hospital for Officers, Highgate.—A hospital for officers was opened last week in Millfield-lane, Highgate. It adjoins Brookfield House, which affords quarters for the staff. The hospital is composed of specially constructed temporary wooden huts, affording a separate room for each of 20 patients, and has an operating theatre, X ray room, &c. The patients' rooms open on to a balcony, so that they can be wheeled out into the air. The construction cost £5000, the plans having been given free by the architect, Mr. C. W. Ferrier. The cost of upkeep will amount to about £700 a month, of which Sir Alfred Mond, who also contributed £3000 towards the cost of building, has guaranteed £200.

Russian Enterprise: Circulating Country Houses.—The Governor of the Kieff district, we learn from a correspondent, is organising a system of circulating country houses along the Dnieper river zone for sick and wounded soldiers. For a beginning about 70 barges will be equipped, with comfortable quarters for invalids, and suitable medical supplies for them and the staff. The barges will be towed by steamers to the most suitable spots on the course of the river or of its navigable tributaries, there to remain for the periods of time judged expedient.

Australia and the Shortage of Doctors.—On the request of the War Office about 100 Australian medical men left Melbourne for England on March 22nd, and will soon be followed by a complete hospital unit.

Sir Lambert H. Ormsby, senior surgeon to the Meath Hospital and County Dublin Infirmary, past-President of the Royal College of Surgeons in Ireland, late examiner in surgery appointed by the War Office for R.A.M.C. examinations, has been appointed honorary consulting surgeon to the New Zealand Expeditionary Force, with the rank of Lieutenant-Colonel. Sir Lambert Ormsby is a New Zealander by birth, although of Irish parents.

Travel in France.—It is interesting to note that the temporary disorganisation of railway travel in France that resulted from the outbreak of war has now been overcome, at any rate, so far as the route to the South is concerned. The P.L.M. night express between Paris, Marseilles, and the Riviera has resumed its former route and gained three hours on the whole journey. Carriages branch off at Tarascon to serve the Nismes–Montpellier–Cette district; a new night express runs between Paris and Lyons (*viâ*

Dijon), and the day express time is shortened by two hours; while extensions to Geneva and to Grenoble, Modane, Turin, and Rome of the Paris-Lyons service facilitate communication with Switzerland and Italy. These changes came into operation on March 23rd.

A New Red Cross Hospital for Honiton (Devon).—At Honiton last week the Mayor formally opened the Voluntary Aid Red Cross Hospital provided by the district. It contains two wards, with 30 beds, operating theatre, &c.

Medical News.

Victoria University of Manchester.—At examinations held recently the following candidates were successful:—

Third M.B. and Ch.B. Examination.

E. R. Gilmore, J. B. Leigh, and B. L. Lloyd.

Second M.B. Examination.

Frances G. Bullough, James Charnley, R. S. Paterson, and H. T. Savage.

Diploma in Public Health.

T. F. Bamford, A. G. Bryce, D. I. Dakeyne, H. H. Proudfoot, and D. M. Wilson.

Diploma in Dentistry (Third Examination).

W. K. Lever and Herant Papazian.

Diploma in Dentistry (Second Examination).

Dental Metallurgy.—B. C. Betts, Roland Critchley, John Green, James Kershaw, H. A. Parkinson, George Stirling, A. C. Tattersall, and C. H. Travis.

Dental Mechanics.—B. C. Betts and James Kershaw.

Dublin University School of Physic, Trinity College.—At the recent Hilary examinations the following candidates were successful:—

Preliminary Scientific Examination.

Chemistry and Physics.—Patrick Casey and Athanas Blagoff.

Botany and Zoology.—William Swirles Allardyce.

Intermediate Medical Examination.

Part I., Anatomy and Institutes of Medicine (Physiology).—Patrick Bernard Moloney, Thomas Scannel McDonald, Herbert James Wright, Thomas Edward Hill, Thomas Mulock Bentley, Wilfred Vincent Pellissier, Arthur Isaac Steyn, Harry Banks, William Andrew Byrn, Fleetwood William Porter Sullivan, Meta Grace Jackson, William Joseph Hamilton, and John Edmund Hill.

Part II., Applied Anatomy and Applied Physiology.—William Robert Fearon, Edward D'Arcy McCrea, Stanley Cyril Mitchell, Andrew Hope Davidson, Alexander Richard Barlas, Edward Oswald Marks, George William Bernard Shaw, Willem Petrus Lubbe, Henry James Rice, Alan Glynn Wright, Frederick Joseph Smith, Joseph Roland Brennan, Bryan Austin McSwiney, Michiel Dippenaar, Rita Henry, Patrick Rocks, Robert Wallace Nesbitt, Charles Perceval Chambers, William James McClintock. Hirsh Brill, Philip Hall, Joseph Godfrey Bird, Eileen Gertrude Gwynn, and Marie Annette Hadden.

Final Examination.

Part I., Materia Medica, Medical Jurisprudence, and Hygiene and Pathology.—Charles Owen James Young, Arthur Hubert Watson, Frederick John Murphy, Clotilda Bayne Bevis, William Lionel Bates, John Thorp Westby, Edward Lipman, Roland Harris Graham, Edward Parker and John James Keatley (Materia Medica and Pathology), Henry Stephen Campion (Medical Jurisprudence and Hygiene and Materia Medica), Rupert Montgomery Gordon, John Armstrong Crozier Kidd, Thomas Edward Beatty and William Hunt (Materia Medica, completing examination), and Thomas Galvin Roche and Grosvenor Leyburne Murphy (Pathology, completing examination).

Part II., Surgery.—John Speares, Herbert McWilliam Daniel, Eugene John McSwiney, Arthur Cyril Bateman, James Salmond Robinson, Andrew William Palethorpe Todd, George Stanton, Edward Mannix, Francis Albert L'Estrange, Clara Beatrice Marguerite Adderley, William Blacker Cathcart, Henry Ireland Gascoyne Rutherford, and Kathleen Dorothea Wallace.

Part II., Medicine.—Joseph Victor Cope, John Speares, Francis Sidney Mitchell, John Milo Ryan, Arthur Cyril Bateman, Isaac Whitla Corkey, William Blacker Cathcart, William Fothergill Wilson, Hilda Varian, Norman McConnell Boyce, Edmond Robinson, William McElrea Snodgrass, Geraldine Murphy, Edwin Boyers, James Salmond Robinson, Joseph Henry Cranston Walker, and Christopher Charles Albertyn.

Part II., Midwifery.—William Fothergill Wilson, George William Doran, Frederick Rowland Studdert Shaw, Thomas Stanton, Godfrey Bateman, William James Dowling, Evelyn Ross, Thomas Edward Bellingham Beatty, George Oliver Fairthough Alley, Edward Gordon Fishe, Arthur George Fisher, Grosvenor Leyburne Murphy, William Benjamin Walker, Richard William Acheson, and Cecil Francis Brady.

Intermediate Dental Examination.

Anatomy and Physiology.—John Henry James Stuart and Henry Erasmus Flavelle.

Final Dental Examination (B. Dent. Sc.).

Hugh Theodore Alexander McKeag.

Diploma in Public Health, First Examination.

Walter Crane and Edward Harnett Patrick Murphy.

Experimental Physics.—Frederick William Robertson, James Sinclair Quin, Joseph Cecil Gillespie, John Gerard Holmes, Richard Counihan, Thomas Madill, Richard William Shaw, Ivan Wakefield Beatty, John Henry Brunell Crosbie, Patrick Joseph Duggan, Cecil Emrys McQuade, John Charles Joseph Callanan, William Joseph Orr, Derrick Haughton Gardiner Fishbourne, Richard Wood Power, Johannes Tobias Mynhardt, Cecil Joseph Quinlan, Gerald Fitzmaurice Keatinge, Henry Allman Lavelle, William Joseph Hogan, Richard Dominick Murphy, Albert Hugh Thompson, William Swirles Allardyce, John Cecil St. George Earl, Gertrude Rice, Read Abgar Aidin, Herbert Birney, Leo Vincent Clifford, John Henry Coolican, Albert Victor Foster, Becker Fitzjames Haythornthwaite, Noelle Long, Edward Henry Montgomery, George Francis Thomas Saunders, John Farneworth Sheppard, Jacobus Frederik Van Staden, and Thomas James Russell Warren.

University of Durham Faculty of Medicine.—At examinations held recently the following candidates were successful:—

First Examination for the Degree of Bachelor of Medicine.

Samuel Eric Hill Anderson, John Maurice Brydson (second-class honours), Sujan Raj Chatterji, Iris Marjorie Cheeseright, Eskander Girgis, Ibrahim Girgis, Mary Isabel Alleyne Grimmer, Gabriel Jonas Dowuona Hammond, Reginald Arthur Hickley, Donald Falconer Hocken, James Richard Hughes (second-class hononrs), Louis Lavine, David Levinstein, Ahmed Saleh, Hans Wilhelm Walther, and George Roebuck Woodhead.

Third Examination for the Degree of Bachelor of Medicine.

Materia Medica, Pharmacology, and Pharmacy; Public Health; Medical Jurisprudence; Pathology and Elementary Bacteriology.—Norman Alexander Martin, George Nathaniel Metzger, and Alfred Smirthwaite.

Death of Mr. Francis Arthur Knox Stuart, B.A., L.S.A. Lond.—A promising career was prematurely ended by the untimely and tragic death on March 9th of Mr. Francis Arthur Knox Stuart at a Chichester nursing home, whither he was removed following a serious motor accident. While riding a motor-cycle, to which a side-car was attached, on the Chichester—Arundel road on Feb. 23rd he accidentally collided with a motor-car belonging to an Arundel medical man and sustained a compound fracture of the right leg. He never recovered from the shock; the limb was amputated, and death occurred on March 9th. Born on Sept. 27th, 1875, Mr. Stuart studied at Cambridge, where he took the B.A. degree, and at St. Mary's Hospital, London, becoming L.S.A. Lond. in 1907. At Cambridge he won distinction as a cycle-track rider and gained many trophies, while he was also an enthusiastic golfer. At the time of his death he was the senior medical officer of the West Sussex Mental Hospital at Graylingwell, Chichester. Those associated with Mr. Stuart at the hospital express profound sorrow at the untimely end of one who was held in the highest esteem in the cathedral city and district. The funeral took place at Chichester on March 12th, a service in the chapel on the hospital estate preceding the interment.

Resignation of Dr. R. A. Birdwood.—Dr. Birdwood, who has just retired from the post of medical superintendent of the Park Hospital, Hither Green, after 37 years' service under the Metropolitan Asylums Board, has been responsible for many reforms in the working of the service. He carried out the scheme by which small-pox patients were taken direct from their homes to ships moored down the river, and he initiated diet scales which have resulted not only in a lessened mortality, but also in a decrease of expenditure. His views were not always supported in the beginning, but experience proved to be on his side.

Liverpool Reformatory for Girls.—Owing to an outbreak of infectious disease among the inmates of this institution the Home Secretary has certified that the premises at 36, Carlton-road, Tranmere, Birkenhead, are fit to afford temporary accommodation, six months from the date of the certificate, March 3rd, for not more than 90 girls of the reformatory.

Society for the Study of Inebriety.—The annual meeting will be held in the rooms of the Medical Society of London, 11, Chandos-street, Cavendish-square, W., on April 13th, at 4 p.m. Dr. H. Crichton Miller will open a discussion on Dual Personality and Intemperance. Each member and associate is at liberty to introduce a visitor.

Dr. Philippe Briffaux, of the University of Louvain, has been appointed house surgeon at the Dover Royal Victoria Hospital.

We regret to announce the death of Mr. Bernard Roth, F.R.C.S., which took place on March 29th.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Harris, John Henry, M.D. Durh., M.R.C.S., L.S.A., D.P.H. Cantab., Major, R.A.M.C. (T.), has been appointed Specialist in Surgery to the 4th Wessex Brigade, R.F.A., whilst temporarily stationed in India.

McDade, C. E., M.D. R.U.I., has been appointed Medical Officer of Health for the Borough of Battersea during the absence of Dr. G. Q. Lennane.

Oates, G. E., M.D. Lond., D.P.H. Cantab., has been appointed Medical Officer of Health for Ilford.

Scott, W. Macargur, L.A.H. Irel., L.M., L.P.S., has been appointed Medical Officer for the West Division of Liverpool.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

Barrow-in-Furness, North Lonsdale Hospital.—House Surgeon. Salary £150 per annum, with residence, board, and laundry.

Bath, Royal United Hospital.—Resident Medical Officer.

Birkenhead Borough Hospital.—Senior House Surgeon. Salary £120 per annum, with board and laundry. Also Junior House Surgeon. Salary £100 per annum, with board and laundry.

Birmingham General Dispensary.—Resident Medical Officer, unmarried. Salary £250 per annum, with apartments, attendance, &c.

Birmingham and Midland Hospital for Skin and Urinary Diseases.—Clinical Assistant for three months. Salary at rate of 52 guineas per annum.

Birmingham, Romsley Hill Sanatorium for Consumptives.—Assistant Resident Medical Officer, unmarried. Salary £250 per annum, with board, apartments, and laundry.

Birmingham, Yardley Road Sanatorium and the Anti-Tuberculosis Centre.—Third Assistant Medical Officer. Salary £200 per annum, with board and residence.

Bootle Borough Hospital.—Senior and Junior House Surgeons, Salary £150 and £130 per annum respectively, with residence. board, and laundry.

Bournemouth, Royal Victoria and West Hants Hospital.—Three House Surgeons for six months. Salary £100 per annum, with board, lodging, and washing.

Breconshire County Council.—Temporary Assistant School Medical Officer. Salary at rate of £300 per annum.

Bridgwater Hospital.—House Surgeon, unmarried. Salary at rate of £125 per annum, with board, lodging, and washing.

Bristol Education Committee.—Female Assistant School Medical Officer. Salary £300 per annum.

Bristol Royal Infirmary.—Three House Surgeons. Two House Physicians, and One Obstetric and Ophthalmic House Surgeon. Salary at rate of £120 per annum, with board, apartments, and laundry.

Burnley County Borough.—Temporary Assistant Medical Officer of Health. Salary at rate of £400 per annum.

Bury Infirmary.—Senior House Surgeon and Junior House Surgeon. Salary £175 and £150 per annum respectively, with board, residence, and washing.

Canterbury, Chartham Asylum.—Locum Tenens Assistant Medical Officer. Salary £7 7*s.* per week, with board, lodging, and washing.

Canterbury Mental Hospital.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, lodging, washing, and attendance.

Chesterfield and North Derbyshire Hospital.—Second House Surgeon Salary £150 per annum, with board, apartments, and laundry.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—Tuberculosis Officer. Salary at rate of £400 per annum, with lunch and dinner. Also Gentleman to supply the place of Members of the Out-patient Staff of Physicians who are on service in H.M. Forces.

Croydon Borough Hospital.—Assistant Resident Medical Officer. Salary £150 per annum, with board, residence and laundry.

Derby, Derbyshire Hospital for Sick Children.—Female Resident Medical Officer for six months. Salary £200 per annum.

Dudley, Guest Hospital.—Senior Resident Medical Officer. Also Assistant House Surgeon for six months. Salary £150 and £120 per annum respectively, with board, residence, attendance, and washing.

Dumfries, Crichton Royal.—Temporary Assistant Physician, unmarried. Salary at rate of 5 guineas a week, with apartments, board, laundry, and attendance.

Edinburgh, Royal Edinburgh Asylum, Morningside.—Assistant Medical Officer. Salary £175 per annum, with board, rooms, &c.

Halifax Royal Infirmary.—Second and Third House Surgeons, unmarried. Salary £120 and £100 per annum respectively, with residence, board, and washing.

Hampshire County Council.—Assistant County Medical Officer of Health. Salary £300.

Hull, Victoria Children's Hospital, Park-street.—Resident House Surgeon and Resident Assistant House Surgeon. Salary £60 and £50 per annum respectively, with board and laundry. Also Resident House Surgeon. Salary £100 per annum, with board and laundry.

Kensington Dispensary and Children's Hospital.—Resident Medical Officer. Salary £100 per annum, with board, apartments, and washing.

Kent County Council.—Tuberculosis Officer. Salary at rate of £500 per annum.

Lancashire County Council, Elswick Sanatorium, near Kirkham.—Medical Superintendent. Salary £300 per annum, with board, apartments, and washing.

Liverpool, Township of Toxteth Park.—District Medical Officer and Public Vaccinator for No. 1 District of the Township. Salary £500 per annum.

London Lock Hospital, Harrow-road, W.—House Surgeon for six months. Salary at rate of £130 per annum, with rooms, full board, and washing.

Luton, Borough of.—Acting Medical Officer of Health. Salary at rate of £500 per annum.

Macclesfield, Cheshire County Asylum, Parkside.—Second Assistant Medical Officer. Salary £300 per annum, with rooms, board, washing, &c.

Maidstone, Kent County Asylum.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, quarters, attendance, washing, &c.

Manchester Children's Hospital, Gartside-street.—Assistant Medical Officer for Out-patient Department for six months. Salary £100 per annum.

Manchester Children's Hospital, Pendlebury.—Resident Medical Officer, unmarried, for six months. Salary at rate of £100 per annum.

Manchester, County Asylum, Prestwich.—Assistant Medical Officer, unmarried. Salary £250 per annum, with board, apartments, attendance, and washing.

Manchester Hospital for Consumption and Diseases of the Throat and Chest.—Assistant Medical Officer and Pathologist. Salary £60 per annum.

Manchester Northern Hospital for Women and Children, Park-place, Cheetham Hill-road.—House Surgeon. Salary £120 per annum, with apartments and board.

Middlesbrough, North Ormesby Hospital.—House Surgeon. Salary £150 per annum, with board, washing, and attendance.

Mile End Old Town Infirmary.—Two Assistant Medical Officers. Salary £275 per annum, with board, lodging, and washing.

Miller General Hospital for South-East London, Greenwich-road, S.E.—Senior House Surgeon for six months. Salary £100 per annum, with board, residence, and laundry.

Newport (Mon.), Royal Gwent Hospital.—Resident Medical Officer. Salary for first six months at rate of £100 per annum, second six months £125, and third six months £150, with board, residence, and laundry.

Northampton County Borough Education Committee.—Dental Surgeon. Salary £250 per annum.

Northampton General Hospital.—House Surgeon. Salary £120 per annum, with apartments, board, washing, attendance, &c.

Norwich, Jenny Lind Hospital for Sick Children.—Female Resident Medical Officer for six months. Salary £150 per annum, with board, apartments, and laundry.

Notts Education Committee.—Female Assistant School Medical Officer. Salary £300 per annum.

Oldham Royal Infirmary.—Surgeon to Ear, Nose, and Throat Department. Salary £50 per annum.

Paddington Green Children's Hospital.—Female House Physician for six months. Salary at rate of £80 per annum, with board, residence, and washing.

Queen's Hospital for Children, Hackney-road, Bethnal Green, E.—House Physician and House Surgeon for six months. Salary £100 per annum, with board, residence, and washing.

Royal Hospital for Diseases of the Chest, City-road, E.C.—House Physician for six months. Salary at rate of £75 per annum, with board, lodging, and washing. Also Tuberculosis Officer. Salary £420 per annum.

Royal National Orthopædic Hospital, 234, Great Portland-street, W.—Resident House Surgeon. Salary £100 per annum, all found.

Royal Waterloo Hospital for Children and Women, S.E.—Senior and Junior Resident Medical Officers. Salary at rate of £150 and £100 per annum respectively, with board and washing.

St. Mary's Hospital for Women and Children, Plaistow, E.—Junior Resident Medical Officer for three months. Salary at rate of £90 per annum, with board, residence, and laundry.

Salford Royal Hospital.—Junior House Surgeon and Casualty House Surgeon for six months. Salary at rate of £100 per annum each, with board and residence.

Salisbury General Infirmary.—House Surgeon and Assistant House Surgeon, unmarried. Salary £100 and £75 per annum respectively, with apartments, board, lodging, and washing.

Salvation Army Mother's Hospital, Clapton, N.E.—Female Resident Medical Officer.

Scarborough Hospital and Dispensary.—Senior and Junior House Surgeons. Salary £100 and £80 per annum respectively, with board, residence, &c.

Sheffield City Hospitals.—Infectious Diseases and Tuberculosis Medical Officer. Salary £250 per annum, with board, lodging, and washing.

Sheffield Royal Hospital.—Assistant House Surgeon and Assistant House Physician.

Sheffield Royal Infirmary.—House Surgeon and Assistant House Physician. Salary £100 per annum, with board and residence. Also Assistant House Surgeon and Assistant House Physician.

Sheffield University.—Joseph Hunter Chair of Pathology.

Shoreditch Infirmary, Hoxton-street, N.—Senior Assistant Medical Officer. Salary £280 per annum, with board, apartments, and washing.

Shrewsbury, Royal Salop Infirmary.—House Physician. Salary at rate of £110 per annum, with board and apartments.

South Shields, Ingham Infirmary and South Shields and Westoe Dispensary.—Junior House Surgeon. Salary £115 per annum, with residence, board, and washing.

South Shields Union.—Medical Officer of Harton Institution, Infirmary, and Cottage Homes at Cleadon. Salary £350 per annum, with rations, apartments, and attendance. Also Assistant Medical Officer. Salary £250 per annum, with rations, apartments, attendance, and laundry.

Stockport Union, Stepping Hill Hospital.—Resident Assistant Medical Officer. Salary £250 per annum, with apartments, rations,

Stoke-on-Ttent County Borough.—Female Medical Officer. Salary £300 per annum.

Taunton and Somerset Hospital, Taunton.—Senior House Surgeon. Salary £120 per annum, with board, lodging, and laundry.

Ventnor, Isle of Wight, Royal National Hospital for Consumption and Diseases of the Chest on the Separate Principle.—Assistant Resident Medical Officer, unmarried. Salary £150 per annum, with board and lodging.

Wakefield, Clayton Hospital—Female Junior House Surgeon. Salary £120 per annum, all found.

Warrington Infirmary and Dispensary.—Junior House Surgeon. Salary at rate of £120 per annum, with board, apartments, and laundry.

West End Hospital for Diseases of the Nervous System, Paralysis, and Epilepsy, 73, Welbeck-street, W.—Honorary Registrar. Also Clinical Assistants to Out-patients' Physicians.

West Ham and Eastern General Hospital, Stratford, E.—Junior House Surgeon. Salary at rate of £100 per annum, with board, residence, and washing.

West Riding of Yorkshire.—Temporary Dispensary Tuberculosis Officer. Salary £400 per annum.

Weston-super-Mare Hospital.—House Surgeon. Salary £120 per annum, with board, residence, and laundry.

Births, Marriages, and Deaths.

BIRTHS.

Evans.—On March 23rd, at Fairfield Mount, Chesterfield, the wife of Thomas R. Evans, M.D., of a daughter.

Suckling.—On March 28th, at 5, Marine Terrace, Margate, the wife of John Jerome Suckling, M.B., B.S. Lond., of a son.

Swan.—On March 26th, at Wimpole-street, the wife of R. H. Jocelyn Swan, M.S. Lond., F.R.C.S. Eng., of a son.

Whitney.—On March 27th, at High View, Maldon, Essex, the wife C. Underwood Whitney, L.R.C.P., M.R.C.S., of a daughter.

MARRIAGES.

Martin—Hunt.—On March 22nd, in Scotland, Gerald Noel Martin, Surgeon, R.N., to Agnes Margaret, third daughter of the Rev. R. G. Hunt, vicar of St. Mark's, Wolverhampton.

Tylecote—Boddan.—On March 27th, at St. James's Church, Birkdale, Frank Edward Tylecote, M.D., D.P.H. Vict., M.R.C.P. Lond., Captain, R.A.M.C. (T.), to Charlotte Dora, only daughter of Mr. and Mrs. Boddan, of Hutton Dene, Heaton Mersey, and York-road, Birkdale.

DEATHS.

Macfie.—On March 26th, at his residence, St. George's-road, Bolton, Charles Macfie, M.D., aged 65 years.

McKerrow.—On March 23rd, George McKerrow, M.B., C.M., at Barns-street, Ayr, aged 65 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

BOOKS, ETC., RECEIVED.

Notes, Short Comments, and Answers to Correspondents.

HEALTH OF UGANDA.

Sir F. J. Jackson, G.C.M.G., C.B., Governor of Uganda, has forwarded to the Colonial Office for presentation to Parliament a report on the Blue-book of that Protectorate for the year 1913–14. The report states that the population in March, 1914, was estimated at 2,909,122, including 1017 Europeans, (761 males and 256 females) and 3651 Asiatics. Amongst Europeans in 1913 there were 4 marriages, 25 births, and 9 deaths. The health of European officials was, on the whole, satisfactory. The average number resident during the year was 289, amongst whom there were 485 cases of illness and no deaths, as compared with 395 cases and 5 deaths during 1912. Of the admissions to hospital 155 were due to malaria, 4 to blackwater fever, and 101 to digestive diseases. The number of officers invalided since 1906 (inclusive) has been 32, the principal causes of invaliding being nervous and mental diseases (9 cases), blackwater fever (5 cases), circulatory affections (5 cases), and general debility (6 cases). A large number of cases of illness amongst the general European population are treated at the central hospital of the Church Missionary Society at Mamirembe, and statistics relating to these are not available. At Government Hospitals there were 953 cases treated, the principal disease being malaria (325 cases) and digestive diseases (196 cases). The special report on blackwater fever, which relates to all hospitals, shows 19 cases with 2 deaths, as against 9 cases and 3 deaths in 1912. The number of blackwater fever cases has increased during the last five years, but this is believed to be due entirely to the rapid increase in the susceptible population, which has outstripped the suitable housing accommodation. It was noticed that amongst Government officials, who, as a body, are comparatively better situated as regards housing, mosquito protection, and general condition of living, there was no increase of incidence and the death-rate was lower.

Returns of births and deaths amongst natives are not obtainable, but in certain districts approximate figures are supplied by the native chiefs. In the districts concerned these show a birth-rate of 24·93 per 1000 and a death-rate of 22·41. The highest birth-rate (44·6) occurs in Busoga district and the lowest (12·87) in Buganda district. The diseases which call for special attention in the native population are plague, sleeping sickness, tick fever, and leprosy. Plague prevails mainly in the Eastern province, though it occurs also in Buganda and in the districts west of the Nile. The number of deaths from this cause was 3734 in 1911, 3100 in 1912, and 3292 in 1913. Of the latter total 2154 occurred in the Eastern Province. There is no doubt that the disease has spread further afield in this Province, more particularly in the districts north of Lake Kioga. It is probable that the establishment of the cotton industry, which is instrumental in bringing very large numbers of natives together at the cotton markets, has been partly responsible for this. Moreover, it is believed that seed cotton is very well adapted to the harbouring of plague fleas, though there is some difference of opinion on this point. Preventive measures adopted are inoculation of contacts and of the population in epidemic areas with Haffkine's serum and the destruction of rats, for which a small reward is offered. The movement of seed cotton is also regulated to minimise, as far as possible, the danger from this source, and the erection of cotton ginneries in the thickly populated areas within the limits of townships is not now permitted. During 1913 there was no very serious local epidemic, but at the time of writing the report the disease had appeared in epidemic form in the port of Jinja. The population to be dealt with is spread over a very wide area and consists mainly of somewhat "raw" tribes, amongst whom it is extremely difficult to ensure that even the most elementary precautions will be taken upon the appearance of an outbreak. To combat this difficulty native "inspectors" have been appointed whose duty it is to report immediately the appearance of suspicious cases and to educate the village chiefs in the precautionary measures which can be taken by them.

The decrease in the number of cases of sleeping sickness continues, and is believed to be general, though it is less marked in Busoga and in the districts surrounding Lakes George and Edward. The deaths attributed to this disease in combined native and official returns numbered 708 in 1913, as compared with 932 in 1912. In 1905 the deaths in the Buganda province alone numbered 8003. Although the spread of this disease has been kept in check, this is entirely due to preventive measures, and the conditions favouring its transmission are still in existence. During the year Miss M. Robertson, protozoologist, reported the presence in the Bunyoro district of a trypanosome not previously observed, resembling morphologically the T. rhodesiense, which is responsible for this disease in Rhodesia and Nyasaland. It is important to ascertain whether this trypanosome is, or is likely to become, pathogenic to man, and investigations on this point are now proceeding. So far the balance of evidence is against the conclusion that this or any other form of trypanosome infecting cattle or game in this area is a new introduction, and there is no evidence that any human being has been infected with this trypanosome.

The number of admissions to hospital on account of spirillum fever has decreased, and it is hoped that the improvement may be maintained. The disease is transmitted by a tick which finds its habitat in mud walls and in old grass huts. It is therefore especially common at wayside camps and markets where carriers gather in considerable numbers. The increase in mechanical transport has, no doubt, been partly responsible for the decrease. European travellers, by the exercise of a little care, can usually avoid contracting this disease. An attempt was made to arrange for the segregation of lepers in special settlements under the supervision of the local chiefs, but this has not proved satisfactory, and the experiment of segregating them in their own villages is now being tried. There is no reason to suppose that leprosy is on the increase. Several local outbreaks of small-pox occurred, but there was no serious epidemic. The deaths from this cause numbered 637 in 1910, 1044 in 1911, 519 in 1912, and 337 in 1913. The number of vaccinations in 1913 was 4535. The best results were obtained with local lymph made in Nairobi.

The laying out of townships and the type of building permissible have formed the special object of the sanitary authorities' attention. The general policy adopted is the reservation of a zone of 300 yards between the business and residential quarters and of a further zone of 300 yards between the European and Asiatic quarters. In new townships this is a fairly simple matter, but there is great difficulty in applying the scheme to townships where long leases have been granted and permanent buildings erected. Anti-malarial gangs are now employed at all the principal stations, who visit all compounds in search of empty tins and other receptacles likely to contain larvæ and examine gutters and water barrels and report the existence of breeding places of mosquitoes. Much improvement has also been effected by the planting of short grass and removal of jungle and scrub near the stations.

The average rainfall at 37 stations for the last 10 years is given as 43·21 inches. In the year 1913 the highest rainfall was registered at Kumi, in the Teso district, and totalled 60·20 inches, distributed over 100 days, the wettest month being May, when 12·49 inches fell. The lowest rainfall was at Mbarara, which showed 20·93 inches falling on 85 days. The rainfall at Entebbe was 56·43 inches, registered in 149 days. There is great local variation from year to year and considerable difference in the rainfall at stations not many miles apart. The "rainy seasons" are by no means regular in their occurrence, but, generally speaking, heavier rains may be expected to occur between the end of March and the middle of June, and again between the beginning of September and the end of November. The highest temperature recorded during 1913 was 104° F. at Masindi in November, and the lowest 47° F. at Fort Portal in October. The mean maximum for the year at Entebbe was 79·7° and the mean minimum 62·7°.

CHEMICALS IN RUSSIA.

RUSSIA has for a number of years chiefly made fuming sulphuric acid, sulphur salts, superphosphates, potash, alum, sulphate of soda (largely used in the glass works), muriatic acid, nitric acid, and on a small scale tin salt, lead salt, nitrites, a number of earth and other colours, tartaric acid, oxalic acid, tartar emetic, and prussiate of potash. During the last 12 years Russia has also introduced the production of toluol, trinitro-toluol, nitro-benzol, benzol, liquid oxygen, carbide of calcium, lactic acid, acetone, iodides of potassium and sodium, bromides of potassium and sodium, other iodine and bromine preparations, peroxide of hydrogen, chloroform, a series of new aniline dyes, chemically pure sulphuric, muriatic, and nitric acids, sulphide of carbon, gold and platinum salts, antimony salts, and salicylic acid. The Russian chemical industry is very irregularly distributed over the country, but the chief centres are Petrograd, Moscow, Odessa, and some of the Western Provinces. Sulphur is found in the south-east (Caucasus) and the north-east (Ural). Phosphates are plentiful in the south-west, and are in great demand for manures. The Russian Department of Agriculture has allowed the importation duty free of certain chemicals to help farmers in the eradication of field pests, namely Schweinfurth green, blue copperas, bird-lime, and bisulphide of carbon. Aniline oil and salts have been produced, but the aniline dye industry has progressed very slowly. Soap and Russian soda products are much dearer than in Germany and England.

A WARNING.

Messrs. E. and S. Livingstone, of Edinburgh, inform us that they have had complaints that medical men in Kent and Surrey have been induced by a man calling himself Johnstone to order and pay for one or more volumes of a book entitled "International Medicine," or "International Clinics," which he stated was published by "Livingston and Co.," of Teviot-place, Edinburgh. Messrs. Livingstone have put the matter in the hands of the police, and write to warn medical men that they employ no canvassers and do not publish a work with such a title. The canvasser is described as tall, thin, fair, with moustache, about 45 or 50 years of age. He carried a bag containing printed pages purporting to be samples and was shabbily dressed.

INFLUENZAL LARYNGITIS; MORBILLAR BRONCHO-PNEUMONIA; VERMIN IN THE TRENCHES AND ELSEWHERE.

IT is both curious and instructive to note how old methods arrive again as novelties. A lay correspondent writing from Manchester concerning the treatment of influenzal laryngitis gives us as a result of his own personal experience that "a gargle, consisting of one drop of iodine in a wineglass of water, swallowed after gargling, three times a day, has cured the above complaint in a couple of days." A gargarisma iodi used to be contained in many hospital pharmacopœias and possibly is now. A sherry-coloured solution of tincture of iodine in water was frequently recommended, both as a dressing and as a gargle, the latter to be swallowed after gargling. One drop of the tincture is a rather small dose—two or three would perhaps be better—in a wineglassful of water, but we are quite prepared to believe that the treatment mentioned would prove of service.—Mr. R. Bazett also writes to call our attention to "an obvious line of treatment" which he has always used in measles, a disease now more or less epidemic in London and elsewhere. The method is to paint the tonsils with a mixture of 5 to 10 minims of liquid carbolic acid with the same quantity of the old tinct. iodi in half an ounce of glycerine. He has never had broncho-pneumonia supervene in a case in which this treatment has been used from the start. The treatment has had considerable advocacy already.—Finally, Mr. John Frederick Briscoe calls attention to the danger of toxic effects attendant on the resuscitated practice of powdering the clothing with mercurial salts as a preventive of vermin, not only in the trenches but anywhere. He considers sulphur preferable as being well tried and of known utility against the epizoa (THE LANCET, Feb. 20th, p. 416), useful also against rheumatism, and when mixed with grease for scabies; while for pediculi capitis the white precipitate ointment is still the best.

HEALTH AND CLIMATE OF ST. VINCENT.

THE Hon. C. Gideon Murray (Administrator), in his report for the year 1913–14, states that the population of the island of St. Vincent is now estimated at 46,605. The births during the year numbered 1766, 61·32 per cent. of which were illegitimate, and the deaths totalled 801. The causes of death were:—General diseases (including syphilis, 96; tubercle, 51; tetanus, 10; malarial fever, 1; dysentery, 11), 211; diseases of nervous system, 32; of circulatory system, 24; of respiratory system, 51; and of digestive system, 156; parasites, 20; age, 88; stillborn, 111; other diseases, 108. During the year there were 842 cases treated in the Colonial Hospital, the death-rate being 3·92 per cent. of the total cases. The medical officer is greatly assisted in his work by the presence of an efficient European nurse-matron, selected by the Colonial Nursing Association. There were 9 inmates in the leper asylum on March 31st, 1914. Under the Public Health Ordinance, 1910, provision is made for the compulsory segregation of pauper lepers. The colony's paupers are housed in the old military buildings at Fort Charlotte. They numbered at the close of the year 79. Chronic tertiary syphilis accounts for the vast majority of cases to whom this institution offers asylum for the closing stages of their life. In the towns the authorities are realising more and more the importance of stricter sanitation and are taking steps accordingly. In the villages, however, sanitary matters are still on a primitive basis, although the Government, through their district sanitary and medical officers, spare no pains to impress upon the population generally the necessity for care in this direction.

The mean monthly temperature in 1913–14 was 78·5° F., the maximum being 80·5° in September and the minimum 73·3° in January. The rainfall for the year was 88·3 in.; rain fell on 247 days, and the maximum fall in 24 hours was 3·40 in. on Oct. 24th. Except in August and September, when the atmosphere is uncomfortably hot, although not even in those months insalubrious, the climate may be regarded as most healthy for both Europeans and coloured persons. Malaria is hardly known, while yellow fever has proved itself to be a disease of the past. "St. Vincent," adds the Administrator, "is one of the beauty spots of these West Indian Islands. With its exquisite scenery, its lovely drives, rides, and walks, its healthy climate, it cannot fail at the conclusion of the great and fearful war which at present envelopes Europe to attract to its shores some of the numerous tourists who in winter seek warmth and sunshine and an escape from the colder northern climes."

R. G. P.—The Section in question of the Medical Act applies to New Brunswick, Nova Scotia, Prince Edward Island, and Quebec. Ontario has made a move which should lead to Canadian reciprocity, as the example of Ontario will probably be followed by Manitoba and Western Canada. It is an anomaly that we have not yet attained to general reciprocity with Canada, and one that has proved inconvenient in supplementing our medical service with the Expeditionary Forces.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY, Society's Rooms, West London Hospital, Hammersmith-road, W.

FRIDAY.—8 P.M., Clinical Meeting. Cases will be shown by Dr. F. S. Palmer, Mr. McAdam Eccles, Dr. G. Pernet, Dr. R. Morton, Mr. O. Addison. and Dr. A Saunders.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.
THURSDAY.—5.15 P.M., Clinical Lecture.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

An Address
ON
WOUND INFECTIONS
AND ON
SOME NEW METHODS FOR THE STUDY OF THE VARIOUS FACTORS WHICH COME INTO CONSIDERATION IN THEIR TREATMENT.

Delivered before the Royal Society of Medicine on March 30th,

By COLONEL SIR A. E. WRIGHT, M.D., F.R.S.,
A CONSULTING PHYSICIAN TO THE EXPEDITIONARY FORCE.
(*From the Research Laboratory attached to No. 13 General Hospital, Boulogne-sur-Mer.*)

THERE are a number of quite elementary problems which must be solved before we can arrive at any effective treatment of wound infections. A very brief consideration of the facts will bring us face to face with the questions to which we have to find an answer.

EVOLUTION OF WOUND INFECTIONS.

In this war practically every wound is heavily infected. The chain of cause and consequence seems to be as follows. The clothes and skin of the soldier on war service become contaminated with all manner of filth containing pathogenic organisms and spores; the projectile takes these with it, and it implants them far beyond the reach of any prophylactic applications of antiseptics.

A cultivation medium is now provided by the blood and lymph which are poured out into the track of the projectile; and we find in the wounds—I have in view here wounds examined immediately after arrival at the front—a mixed infection of a streptococcus with microbes derived from the fæces. This fæcal infection is a special outstanding feature in this war.

Among many species of intestinal microbes which have been found in wounds two have a quite special importance. One is the *gas-phlegmon bacillus*, or *Bacillus aerogenes capsulatus* of Welch—a large Gram-staining anaerobic and actively gas-forming microbe. It is found both in infiltrated superficial wounds and in deep wounds, and is particularly abundant in the frothy and offensive fæcal-looking discharges which anaerobic wounds furnish. The other is the tetanus bacillus. It is more rarely encountered, and is also much less abundant in the discharges. Sometimes, however, it may show up in every field of the microscope.

The presence of the streptococcus and these two fæcal microbes makes the first period of the wound infection—the period of imprisoned discharges—a specially critical time for the patient. During this the streptococcus may invade the tissues, and set up a cellulitis or, more rarely, erysipelas. Or the tetanus bacillus may find opportunity to grow out and manufacture its poison and induce tetanus. Or the bacillus of Welch may make its way into the body and set up a gas-phlegmon in the region round about the wound, and an obstructive gangrene in the distal portion of the limb. Or, again, the bacillus of Welch and the streptococcus may join forces, and may in conjunction produce the gas-phlegmon or cellulitis.

As soon as a free outlet has been provided, and aerobic conditions have been established in the wound, its bacterial flora changes. The ordinary pyogenic infection which has, up to this, been in abeyance, now gains the upper hand, and instead of an "*infection of the imprisoned discharges*" or, as the case may be, "*an infection of tissues*," we have now an "*infection of the granulating wound surfaces, and of the flowing discharges.*" The chief bacterial agents here at work are the streptococcus and staphylococcus, and bacillus proteus.

This pyogenic infection may, after lapse of time, subside, the wound healing up when this occurs; or the mixed infection may narrow itself down to a streptococcic infection and become chronic, the wound in this case remaining open indefinitely in the form of a discharging sinus. Or, lastly, when there is an obstructed outflow the infection may go from bad to worse, until the patient succumbs to continued suppuration and septicæmia.

SOME FUNDAMENTAL CONSIDERATIONS IN REGARD TO TREATMENT.

Those are in very brief summary the facts with regard to the evolution of wound infections, and I would venture, in passing on to discuss with you their treatment, to remind you that the ideal we ought to approximate to is the healing of the wounds by *first intention*—that is, without sensible interference by bacterial infection; and that we are so far from the attainment of that ideal that nearly all our wounded are suffering from bacterial infections; that very many are ill of these infections; and that not a few are, through these, in danger of their lives.

We have at disposal for the treatment of these wound infections three different therapeutic measures. Let me enumerate them to you in the order in which they would naturally suggest themselves to you.

First in that serial order would come *treatment by antiseptics*. After this would come what I would propose to call *treatment by physiological methods*. I mean procedures such as the opening and draining of the wound—which bring the antibacterial powers of the blood to bear on the infecting microbes. And, lastly, would come the reinforcement of the antibacterial powers of the blood—i.e., *treatment by vaccine-therapy* and similar methods. I believe it is really beyond all question that of these three the second is beyond all comparison the most important, and I would submit that, all loud talk about antiseptic treatment notwithstanding, this is at best an ancillary method of treatment. And, of course, the same applies also to treatment by vaccines.

Let me also here suggest to you another quite fundamental consideration. It is this. It will be clear that we cannot apply physiological treatment aright, nor can we apply any antiseptic or vaccine to best advantage in wound infections unless we first understand the physiological processes which go on in the wound. We do not understand these yet, even in outline.

It will therefore be necessary to address ourselves to the task of discovering what goes on in the wound and of following out its biological evolution. And the only way of doing this will be to formulate to ourselves in clear terms the questions which want answers; then—for merely looking at the wound will not help—considering how to set to work to get our answers; and, finally, taking cognisance of the results which the experimental methods which I am about to describe to you have already yielded.

No. 4780.

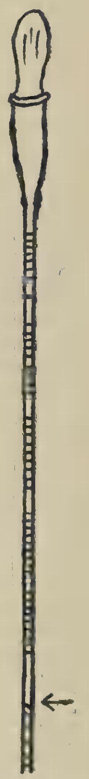
Our first question can be formulated thus:

1. *Can the microbes which are found in wound infections live and multiply in the unaltered blood fluids?*

In other words, if I take pyogenic microbes from the wound and implant these into the normal undiluted serum, will this give me a satisfactory amount of growth? If we are going to carry out this experiment, and to carry it out repeatedly, and deal with a number of different bloods; and if we are going to cultivate directly from the pus, we shall evidently have to work in capillary tubes with very minute quantities of pus and very small quantities of undiluted serum. The technique which I have arrived at for fulfilling these requirements is a very simple one. I may call that technique the *wet-wall method.*

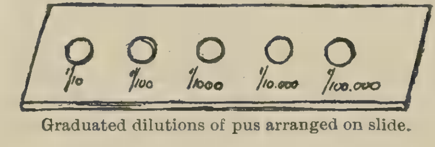
Method of Making Cultivations of Pus in Serum.

FIG. 2.



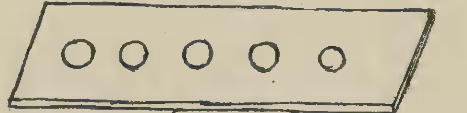
Capillary pipette filled in with five unit volumes of serum, and one unit volume of the last dilution of pus.

FIG. 1 (Slide I.).



Graduated dilutions of pus arranged on slide.

FIG. 1 (Slide II.).



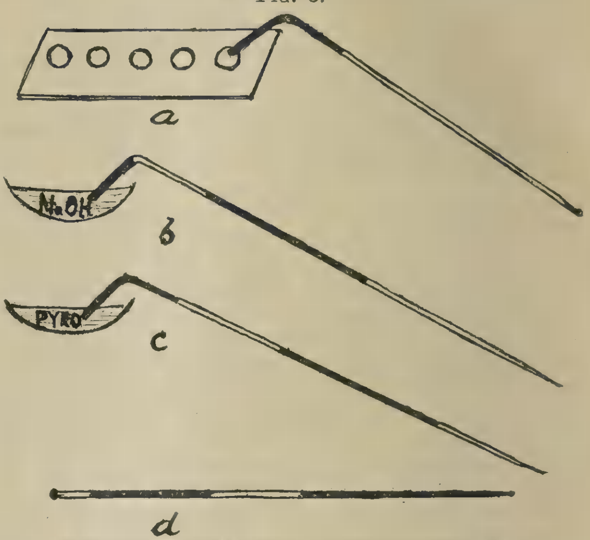
Volumes of serum implanted with the above dilutions of pus.

The first step in the procedure to make by the technique I described in my book on "Technique," a graduated series of dilutions of pus, using for this purpose any indifferent diluting fluid, and arranging the successive dilutions on a slide in the form of a series of drops. I then take in hand a clean capillary pipette fitted with a teat, make a mark upon the stem, and then draw up into it a series of unit volumes of serum, one unit volume of serum for every dilution of the pus. This done, I commence with the highest of these dilutions—that is, the one containing the smallest number of microbes—and draw it up into the stem of the pipette, stopping off exactly at the fiducial mark. I then expel this column, leaving, of course, as I do so the walls wet with a quantum of microbial suspension—a quantum which would correspond roughly to that which would be left on the outside of a platinum wire of similar stoutness dipped into the suspension. I now expel from my capillary tube my first volume of serum—this in passing over the wet wall will take up its charge of microbes—and I receive this as it issues on to a clean slide. I repeat these manipulations with the next lower dilution of pus and the next unit volume of serum, and so on, until I have implanted my series of volumes of serum with my series of bacterial dilutions. At the end I find myself with a series of drops of serum, containing graduated charges of microbes, ranged in order upon a slide, and I have in my hand a pipette which is contaminated up to the point indicated by my fiducial mark. I get rid of this contaminated segment of my capillary stem by resecting this just above the fiducial mark, and I now proceed to draw up into my pipette, separating off by bubbles of air, the whole series of drops of serum, beginning with that implanted with the fewest microbes. After sealing up the distal end of the pipette, and closing the butt end by bringing it down upon a bed of plasticine, the pipette is placed in the incubator. After an interval of 6 to 24 hours it is taken out, and the series of unit volumes are now, for purposes of microscopic examination or culture, expelled from the pipette in the order in which they have been taken up—that is, in succession from the lightest to the heaviest implanted. This is effected by cutting through the proximal end of the stem of the pipette and then the distal end, and afterwards luting the latter airtight into the truncated end of the pipette. The luting is done by rolling a little plasticine into a ball, pressing the capillary stem into this pellet as we hold it between finger and thumb, doubling over the plasticine round the stem, and then invaginating the neck of the pipette into the plastic mass. We can now with a teat expel our series of unit volumes of serum on to a slide, obtaining them in the serial order which avoids the contamination of the lighter implanted with the heavier implanted.

Method of Making Anaerobic Cultures in Capillary Tubes.

When we desire to make anaerobic serum cultures we do not employ the capillary pipette used for the original implanting operations as a receptacle for our series of serum cultures, but employ instead a separate capillary cultivation tube for each unit volume of serum. The capillary cultivation tubes here in question are made as follows: We take a portion of capillary stem, say some 8 cm. long, draw it out at one end in the flame of a by-pass into a hair-fine tube, and then break it off, leaving a certain length of throttle attached. We now introduce the other end of the capillary stem into the flame of our Bunsen, and let gravity bend it round into a syphoning curve.

FIG. 3.



Method for making anaerobic cultures in capillary tubes.

Taking one of these capillary cultivation tubes we bring down the syphon end upon our drop of serum, and let this run in, afterwards tilting the tube so as to take in, as a rear-guard, a good-sized dividing bubble of air. This done, we fill into our tube, by syphonage, from watch-glasses placed conveniently to hand, first a small quantity of pyrogallic acid, and then, without dividing off, a small quantity of caustic soda. We now further incline the tube, and let the contained fluids gravitate down towards the distal end until the serum begins to enter the throttle. At that point we arrest it by sealing the tip, and we finally also seal up the butt end, leaving the mixed pyrogallic acid and caustic soda to do their work, and absorb all the oxygen from the dividing bubble air.

Serum cultures made by this method furnish a very striking and uniform result. We obtain in the cultures implanted with the higher dilutions of the pus a pure culture of the streptococcus, and in the cultures more heavily implanted with the pus the streptococcus mixed with a certain number of other microbes; in particular, a few staphylococci and an anaerobic wisp-like diphtheroid bacillus, which often is abundant in pus, being found both intracellularly and extracellularly. All the other pyogenic microbes appear to be inhibited in undiluted normal serum, and when they put in an appearance it is only after fairly heavy sowings with pus, and comparatively late.

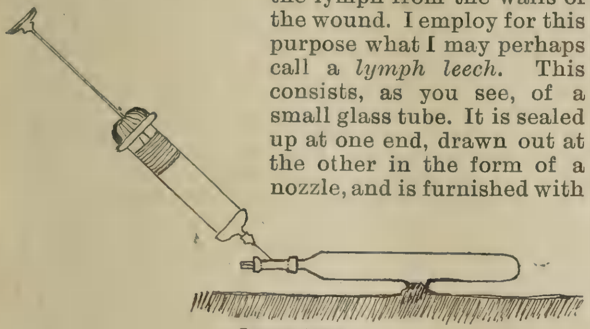
Out of these facts would come what we shall presently see to be a practically important classification of pyogenic microbes—a classification into, on the one hand, *Serophytes*, and, on the other, *Sero-saprophytes*. The serophytes would be those which, presumably because they find their foodstuffs ready made in the blood fluids, are at home there, and can in the absence of phagocytes grow and multiply there without restraint, or practically with restraint.[1] The sero-saprophytes would be those which cannot grow and multiply in the blood fluids until a change which we may, pending nearer investigation, call simply a degenerative change, has passed over those fluids.

What holds true of the blood fluids themselves might perhaps justifiably be assumed to hold true also of the lymph which pours into the wound. None the less, it will be well specially to investigate this point.

2. *Does the lymph which pours into the wound provide a favourable nutrient medium for the microbes which have been growing in that wound?*

To pose this question is already to go a long way towards getting an answer to it. For we can, by the aid of a very simple device, obtain the lymph from the walls of the wound. I employ for this purpose what I may perhaps call a *lymph leech*. This consists, as you see, of a small glass tube. It is sealed up at one end, drawn out at the other in the form of a nozzle, and is furnished with a lateral mouth with a raised rim, the whole being very easily made out of a piece of glass tubing or small test-tube. To the nozzle we fit a piece of fairly thick-walled rubber tubing, and this is blocked at the end with a piece of glass rod. When we want to obtain the exudate from a wound we bring down the lateral opening of the lymph leech upon a granulating surface, and then, transfixing the rubber tube with the needle of a hypodermic syringe, we draw out the air and make a negative pressure. It will be appreciated that the lymph leech is in principle merely a small cupping glass, and that it will, by means of the vacuum, be established in it, hold on tight for whatever period may intervene between dressing and dressing, and furnish an exudate free from all contamination with residual pus left behind in the wound. We can now proceed to compare the fluid in the cavity of the leech with the fluid in the wound outside, or, in connexion with work on antiseptics, to compare the contents of leeches applied respectively to treated and untreated surfaces in the same wound.

FIG. 4.



Lymph leech.

And lymph leeches can also be put to other uses. We can introduce for this purpose with a syringe any fluid we may select into the lymph leech, investigate the effect that fluid exercises upon transudation and emigration. Again, where the nature of a deep-lying infection of a mucous or other surface remains uncertain the application of a lymph leech might clear up the difficulty. We can also, in the case where we are testing the effect of a vaccine upon a wound, take to our aid the lymph leech. For the effect of a vaccine would probably show itself in the exudate in the cavity of the leech long before it would manifest itself in the outside wound. And, lastly, by the application of a lymph leech to the site of inoculation might perhaps help to resolve the problem as to whether or no protective substances are then developed.

But it will be realised that for us at the moment that which is of chief interest is the comparison of the fluid in the cavity of the leech with the fluid in the wound outside.

When, after washing out a heavily infected wound with an antiseptic or simple saline solution, we apply a lymph leech to the walls and then at the next dressing compare the contents of the lymph leech with the fluid outside, we think at first that there must be some mistake. Outside we have an opaque exudate presenting all the ordinary physical characters of pus, containing leucocytes in all stages of degeneration, and swarming with all manner of pyogenic organisms. Inside we have a transparent and slightly blood-stained exudate containing streptococci in practically pure culture, and in addition a few leucocytes, all of which are actively phagocytic. Except in this latter respect, we have, in fact, identically the same result as when we made our thin implantations of pus into normal serum.

The problem now stares us in the face—What is it that makes all this difference between the contents of the lymph leech and the contents of the wound? How has the lymph, which gives in the cavity of the lymph leech a culture of streptococcus, been converted in the wound outside into a fluid which is ideally favourable to the growth of a great number of different species of micro-organisms?

3. *What is the cause of that "corruption of the lymph" which converts it into a favourable nutrient medium for sero-saprophytic microbes?*

The proper way to go to work upon a problem of this kind is to keep it unremittingly before the mind. For then some hypothesis will in the end suggest itself. That found, there will invariably come to notice a certain number of accepted data which the hypothesis will fail to explain. These must then be carefully re-examined to see whether they will stand fast and discredit the hypothesis, or whether they also will come in and support it. And finally, before launching our theory, we ought to think out all its consequences, and then take each of these and verify it.

At any other time one would wish, before promulgating a far-reaching hypothesis, to have verified it at every point. But we have on our hands in Europe, I suppose, already 2 or more millions of wound infections, and every other consideration must give way to that of accelerating the researches, which we must look to to guide us in treating these infections.

I will, therefore, before completing its verification, venture to put before you what is, I believe, the solution of the problem of the corruption of the lymph in the wound.

---

[1] I introduce this qualifying clause because I have on several occasions found the serum of the infected patient to give cultures of streptococcus with a planting of his pus much smaller than that which was required to give a culture in the serum of a normal man.

Let me take my departure from those facts which we were considering a moment ago, relating to the culture of pyogenic microbes in the blood fluids. You will remember that I suggested in connexion with serophytic microbes that these must find all the food materials they require ready formed in the blood fluids, and in connexion with sero-saprophytic microbes that for these no nutrient substances would be available until the albuminous substances of the blood had undergone some sort of preparatory transformation.

I conceive that that transformation could come only by a digestive process. Now, supposing this to be so, there would in the serum come into account a counteracting influence. For we have there an antifermentative, or, as we usually style it, an antitryptic element, which would directly counteract any digestive element which might be struggling to come into operation. And it is clear that microbes which were dependent for their sustenance upon the products of digestive action could establish themselves in the blood fluids only on condition that this antitryptic influence was overborne.

This hypothesis furnishes, as it seems to me, an explanation for certain striking facts relating to the cultivation of microbes on blood fluids, and to bacterial infections. It, as it seems to me, explains the finding that heavy sowings of microbes into serum are effective in giving cultures, while light sowings are not only ineffective, but lethal to the implanted microbes. For it would be only natural that the resistance offered by the antitryptic power of the blood should be overcome by the mass effect of a number of microbes operating upon a restricted or—and this would come into consideration in localised infections—a mechanically isolated quantum of blood. And, again, it would be only natural that the mass effect of a large volume of antitryptic serum could not be overcome by the digestive activities of a very few microbes; and also, I think, in accordance with what we know, that microbes deprived of access to foodstuffs should perish of inanition.

Our hypothesis would also make intelligible, in connexion with infections by sero-saprophytic microbes, that frequent and heavy sowings into the blood should be required before a septicæmia can supervene upon a local infection. And, again, our hypothesis makes it comprehensible that there should be serious difficulty in obtaining hæmocultures, even when the microbes have gained a footing in the blood stream.

And, lastly, our theory brings home to us that, in considering the defence of the body against bacterial infection, we have to take into account not only *active defence* in the form of phagocytes and bacteriotropic substances which make a direct attack upon micro-organisms, but also *passive defence*—that is, protection against infection obtained by preventing microbes converting to their uses the nutrient substances of the blood fluids.

These, however, are general considerations with applications far beyond the sphere of wound infections, and we must return to the particular problem of the corruption of the lymph in the wound.

When, after treating a wound with antiseptics and leaving it clean, we find it a very few hours afterwards teeming with microbes, we are in presence of something which, in my view, urgently stands in need of explanation. For our findings both in the lymph leech and in serum cultures made with the wet-wall method from pus would seem to teach us that the sowing of microbes left behind cannot be nearly heavy enough to produce the voluminous culture found in the wound, nor yet to account for the rapidity with which the sero-saprophytes have started to grow. And, moreover, consideration will bring out that another powerful factor must constantly come into operation in the wound. The factor in question is the tryptic ferment which is elaborated in the phagocytes, and which is, when these break up, discharged into the surrounding medium. This tryptic ferment will come into operation under two different conditions. It will come in whenever a residue of pus—for this would contain free trypsin—is left behind in or afterwards makes its way into the wound. Trypsin will again come into account whenever, after the washing of the wound, leucocytes once more begin to emigrate and phagocytose and break down.

I see in the reduction of the antitryptic power of the lymph thus effected the prime cause of its corruption. Before attempting to obtain confirmation of this from crucial experiments there was a set of findings to be cleared up. I had found in connexion with pus implantations made into serum that when this was heated to 60° C. for ten minutes one no longer obtained the same differential growth of streptococcus as with unheated serum, but obtained instead mixed cultures of streptococcus with sero-saprophytes, in particular staphylococcus and the wisp-like diphtheroid bacillus already made mention of. It seemed at first sight as if this could not possibly be related with a reduction in the antitryptic power of the serum, for it has, in view of the high quality of Opie's work on this question, been generally accepted from him that the antitryptic power of the serum is unaffected by exposure to heat until a temperature approaching the coagulation point of serum is reached. In reality, however, when this is re-investigated quantitatively[2] it emerges that the antitryptic power of the serum is reduced by one-third to one-half when we subject the serum to a temperature of 60° C. for ten minutes.

That difficulty having been removed out of the way of our hypothesis, we may proceed to take cognisance of the results of the crucial test experiments—experiments in which graduated additions of trypsin are made to serum as a preliminary to the implantation of sero-saprophytic microbes. The event of these experiments can be summed up in a sentence. When we add trypsin in quantities sufficient to reduce appreciably the antitryptic power but insufficient to give us any free trypsin, the serum is converted into an eminently favourable nutrient medium for sero-saprophytic microbes.

Our hypothesis is thus very strikingly confirmed. It will be necessary hereafter to follow it into all its consequences. For the present it will, however, suffice if we ponder on the following points. The antitryptic power of the blood would appear to be increased in every case of severe wound infection. We have perhaps here a defensive reaction of the organism directed against a possible invasion of the blood by sero-saprophytes. And we may perhaps look in this direction for an explanation of the non-specific benefit which has been observed to follow upon the inoculation of bacterial vaccines. It is clearly not impossible that the inoculation of a bacterial vaccine might contribute both to active and passive defence—to the active defence of the body against a particular microbe by calling forth a production of specific bacteriotropic substances and to the general passive defence of the organism by calling forth a production of antitrypsin. And these two forms of immunising response would not necessarily be linked together. The production of specific bacteriotropic substances would no doubt depend upon the quantum of bacterial antigen incorporated; while the production of antitrypsin might perhaps depend upon the breaking down of phagocytes and the liberation of their trypsin.

---

[2] The quantitative method here employed was in essentials that described in my "Technique of the Teat and Capillary Glass Tube." It was varied only in the respect that the series of trypsin, serum, and calcified milk mixtures which are employed in that method were taken up, not into a many-stemmed pipette, but into a long, unmounted wide-bored capillary stem, which had, for the purpose of convenient filling in, been bent round at one end in the flame of a Bunsen into a syphoning curve.

(To be continued.)

ROYAL MEDICAL BENEVOLENT FUND.—At the last meeting of the committee 28 cases were considered and grants amounting to £252 were voted to 22 of the applicants. An annuity of £26 was also voted to one applicant. The following is a summary of a portion of the cases relieved:—

Daughter, aged 54, of M.R.C.S. Eng. who died in 1898, and practised at Manchester. Was able to earn her living as a clerk until her health broke down. Only income a pension of £15 per annum from her old employers. The Manchester branch of the Guild have assisted with clothes. Voted £14 in 13 instalments.—Widow, aged 55, of L.R.C.S. Edin. who practised at Dulwich. Husband's long illness absorbed all savings. One daughter, who is being educated by a relative. Applicant suffers from varicose veins and quite unable to work. Voted £10 and referred to the Guild.—L.R.C.P. & S. Edin., aged 65, who practised at Walthamstow, suffering from aphasia and quite unable to do anything. Until recently acted as locum-tenent Married, no children. Voted £18 in 12 instalments.—Widow, aged 61, of M.D. McGill Univ. who practised at Waterloo, Liverpool, and had a very long illness. Five children, ages from 30 to 38. Two sons away from home unable to help, and only income from a daughter who is a clerk earning 30*s*. per week. Other two daughters invalids and require constant nursing. Voted £18 in 12 instalments and referred to the Guild.—Daughter, aged 49, of M.D. Glasg. who practised at Bawtry. Has managed to earn a bare living by taking boarders, but has had none since last autumn owing to the war, and is now in great distress. Voted £10 in two instalments and recommended to apply to the Local War Relief Fund.—M.B., C.M. Edin. who practised at King's Heath, Birmingham. Is married, with one daughter aged 15. Applicant's health and his wife's very unsatisfactory. Has lost nearly all his ordinary and panel patients since the war, and is in great financial straits. Voted £10 and recommended to apply to the local branch of the Prince of Wales' Fund.—Daughter, aged 38, of M.R.C.S Eng. who practised in London. Has earned her own living as governess until health broke down and an operation was necessary a few months ago. Hopes when strong again to resume her work. Voted £5 to take a holiday.—Widow, aged 46, of M.B., C.M. Edin. who practised at Glasgow. Has seven children, ages 6 to 26. Husband was ill for two years before his death and was unable to provide for his family. Son who used to help to keep the home recently disappeared. Earns a little by taking in lodgers and has £12 a year from another charity. Previous relief £52. Voted £20 in 12 instalments.—Widow, aged 60, of L.R.C.P. Edin. who practised at Dumfries. Has two sons, both of whom have joined the army, and two daughters whose total earnings are 18*s*. per week. Previous help six times, £56. Voted £12 in 12 instalments.—Widow, aged 42, of M.D. Aberd. who practised in South Africa. Applicant is suffering from abdominal tuberculosis. Has an annuity of £15 from a charity for incurables; total income only £18. Has two children, ages 14 and 15, both of whom are kept by relatives. Relieved three times, £57. Voted £12 in 12 instalments.—Daughter, aged 66, of M.R.C.S. Eng who practised at Tonbridge. Only income derived from one boarder and £10 per year from a friend, and finds it impossible to make ends meet. Previous relief eight times, £96. Voted £12 in 12 instalments.—L.S.A. Lond., aged 82, who practised at West Kensington and is now blind, and son who lives with him also nearly blind. Other son only able to help slightly. Has a pension of £20 from another charity, also old age pension. Previous relief three times, £20. Voted £12 in 12 instalments.—Daughter, aged 37, of L.R.C.P. Edin. who practised in co. Cavan. Earned her living and was able to assist her mother and invalid sister until she had recently to undergo an abdominal operation. Previous relief some years ago, £10. Voted £10 in one instalment for her convalescence.—Daughter, aged 63, of M.R.C.S. Eng. who practised at Bath. Health very bad, and the little capital left by her father spent in endeavouring to get well. Only income an annuity of £31. Relieved four times, £42 Voted £6.—Daughter, aged 51, of M.R.C.S. Eng. who practised at Holland Park. Health very bad and unable to work. Income only £15 per year and a little assistance from friends. Relieved four times, £37. Voted £12 in 12 instalments.—Daughter, aged 64, of M.R.C.S. Eng. who practised at Great Malvern. Has been able to earn a living as a teacher of elocution, but owing to the war has lost practically all her pupils. Hopes to obtain a paying guest shortly, which will greatly help her. Previous relief twice, £22. Voted £10.

Contributions may be sent to the honorary treasurer, 11, Chandos-street, Cavendish-square, London, W.

WAR AND CHOLERA.[1]

BY W. J. R. SIMPSON, C.M.G., M.D. ABERD., F.R.C.P. LOND.,
PROFESSOR OF HYGIENE, KING'S COLLEGE, LONDON.

AFTER a reference to the remarkable fierceness of the battles, the unfavourable weather conditions, the remarkable absence of scurvy, dysenteries, and epidemic diseases that had so far characterised the present war, Professor Simpson pointed out that the armies of Germany and Austria would be in a very different physical, mental, and material condition in August and the autumn of 1915 or 1916 from what they were in 1914, when victory appeared assured to them. Should epidemics then arise they would not be confined to the particular armies that are first stricken, nor would the civil population in the devastated areas escape. He continued:—

Let us glance for a moment at some of the conditions that will be favourable for the development and spread of epidemic disease. Scarcity of food will add to the hardships of the civil population that have the misfortune to be within the fighting zone, for in this great siege war the destruction of crops and cattle will place large areas much in the position of besieged towns in olden days, while the rise in the price of foodstuffs all round, from the disturbance of ordinary economic conditions and from the fewer people left to till the ground, will weigh heavily on the poor in every country engaged in the war. The many millions of men in arms must be fed. Their main supply will come from their own country, but they will also take what they can get from the invaded countries.

This generation in Europe has been so accustomed to regular supplies from overland or sea by the quick transit afforded by steam power and undisturbed agricultural pursuits, supplemented by a world commerce, that the famines, dearths, and scarcities of an earlier period have been forgotten. Now Central Europe is back, more or less, to a time of isolation plus war on a gigantic scale. The effects of droughts and floods, which assumed importance in times of greater isolation of countries, have under modern conditions been counterbalanced by an inrush of produce from other lands, so that the third partner of soil and seed—viz., meteorology—has been assigned of late a very secondary position, which could only continue while each country has the world to draw on. When this ceases, as it has done for some parts of Europe, meteorology assumes its old sway. The winter, so far as it has gone, has been a particularly wet one, not only at the seat of war but outside of it. In one respect this has been an advantage, because of filling the wells, but the wet season and the purposely flooded lands of Flanders will render the conservation of foodstuffs more difficult than under other circumstances, will accentuate the dearth of food in Europe, and add to the threatening destitution and want. The severe earthquake in Italy, with its 24,000 deaths in one district, will not be without its effect on the physical and mental condition of those in the immediate outskirts of this disaster and who have been subjected to the shock.

A combination of war, flood, and earthquake, ending in famine in some localities and in scarcity of food in others, is calculated to be a powerful force favouring in due season the manifestation and spread of epidemic disease, whether it be typhoid or typhus fever, small-pox, cerebro-spinal disease, cholera, dysentery, malaria, or plague, should the germs of these be present and be conveyed from place to place by any of the armies or refugees.

[1] Abstract of a paper read at the Society of Tropical Medicine and Hygiene, Feb. 19th, 1915.

Cholera Invasions of Europe.

Although cholera is not an endemic disease in Europe, its visitations in the nineteenth and twentieth centuries have destroyed millions of the population. There have been nine invasions of Europe in a little over 90 years. They have varied considerably in their duration, power of diffusion, and severity, the more lengthy ones being distinguished by important recrudescences. Certain localities in Russia, in the neighbourhood of the Caspian Sea, have been so frequently attacked that it is a question whether the disease has established an endemic centre there as it has done in the Far East, in Java, Indo-China, and the Philippines. Although these endemic centres are in themselves a potential danger, it is doubtful whether any of them have hitherto given rise to any considerable diffusion of the disease beyond their own boundaries. The source of the nine invasions in Europe, which have corresponded with similar invasions of the countries in the Far East, has generally been traced to India, though not directly but indirectly, by spreading by land and sea eastwards through the neighbouring countries. On nearly every occasion there has been more than one avenue into Europe, the disease travelling along the chief trade or pilgrim routes in the Near East and radiating in many directions, but there has generally been one principal gateway by which the epidemic has entered Europe, although almost simultaneously there were often others. The interesting and informing reports of the late Dr. Netten, Dr. Radcliffe, and Dr. Barry, and now of Dr. Bruce Low, of the Local Government Board, form a valuable record of the later epidemics.

Professor Simpson then briefly described the nine European invasions of cholera, and epitomised them in the table given below.

European Wars have generally been Free of Cholera.

Notwithstanding the number of invasions of cholera, there have been only three wars in Europe coincident with its presence in the area of hostilities. Cholera was unknown in Europe until a period well after the Napoleonic wars. The first was the Russo-Polish War in 1831. Cholera was very virulent among the troops, and was believed, by the medical men at the time, to have been materially assisted by the war in its dissemination over Europe. The second was the Crimean War, when cholera prevailed over the whole of Europe; and the third was the Balkan War. Cholera was conveyed to the Crimea in transports from France, but it already prevailed in the Russian and Turkish armies. Both the French and the English armies suffered, and it also affected the fleets. The *Timandra*, carrying sick from the Crimea to the Bosphorus, lost 20 the first night from cholera, and between 40 and 50 *en route*. The *Britannia* lost 150 men from cholera in ten days. The most important manifestation in the Balkan War was the outbreak behind the Chataldja lines, where it is estimated there were about 18,000 cases. It was conveyed from there into the Bulgarian army, which spread it among the civil population, through which it passed, and finally the Greek and Serbian armies were affected.

European Invasions of Cholera.

Epidemics in Europe.	Principal entrance gate into Europe.	Interval between each invasion in years.	Number of years continued in Europe.	General characters.
1823	Astrakhan.	—	Less than a year.	Did not travel farther west than Astrakhan. The Persian and Turkish armies, which were at war with one another, suffered severely.
1830–37	Astrakhan.	7	7	Severe and widespread. Very virulent among the Russian and Polish troops. The war was believed to be the great cause of the rapid propagation of cholera in Europe. Great epidemic among the pilgrims at Mecca.
1847–52	Astrakhan.	10	6	Severe and widespread. Invaded a larger area of the world's surface than that of 1830–37, and more deadly. Epidemic at Mecca.
1852–59	Astrakhan.	Nil.	8	More severe and widespread than previous epidemics. On its way through Persia it attacked violently troops of the Shah. Cholera affected the troops in the Crimean War. In 1859 it attacked the French troops in Algeria and the Spanish troops in Morocco.
1865–68 Lingered in Russia till 1874	Constantinople and Southern ports of Europe.	6	10	Severe, but more limited in diffusive power.
1884–87	Marseilles and Toulon.	10	4	Less severe and limited.
1892–96	Baku.	5	5	Less severe and limited.
1905–12	Baku and Astrakhan.	9	8	Comparatively mild and limited.
1912	Constantinople.	—	—	Mild and limited. Prevailed among the Turkish, Bulgarian, Greek, and Servian troops.

Present Position of Cholera in Relation to the Armies.

The danger of cholera prevailing in the zones of hostilities next August is not a remote one. In Europe cholera prevailed in 1914, in Russia in the Province of Podolia; in Hungary in no fewer than 53 different centres; in Austria in 39 centres; in Germany in 10; and in Turkey in 2. In Asiatic Turkey there were two centres on the Black Sea. There is no information about Persia or Arabia, but they are seldom free of cholera, especially during the seasons of the pilgrimages. War will not stop the pilgrimages to Mecca and other holy places.

There is every probability of the existing infections in Europe recrudescing, and although they possess the character of having stayed their time, had it not been for the wars of the past two years, yet there is a risk of them acquiring an exaltation in their strength and powers of diffusion by attacking a population enfeebled by hardship and destitution.

There is also always the risk of Turkish, Russian, and Indian armies bringing from the East to Persia, Egypt, and Europe a new and more potent infection, endowed with greater virulence and capacity for spreading than that of 1913 and 1914.

Moving armies are much in the same position as pilgrims and other crowds travelling from place to place. In the Indian armies the long voyage, the excellent ships they come in, and the sanitary precautions taken, reduce the risk of importation by sea to a minimum, but even here carriers of cholera infection are not totally excluded when thousands have to be transported. The same favourable conditions do not exist on the land routes in Persia and Asia Minor, or wherever the Asiatic troops of the Turks may march. Their condition approximates more to that of the pilgrims. The one hopeful feature against the chances of fresh importation on a large scale is that there are at present no signs of an advancing epidemic from the East. On the contrary, the indications are rather that if there had been no Balkan War, cholera would have disappeared from Europe for a time, as it has done in former invasions. That, however, does not justify neglect of precautions and in not being thoroughly prepared for every contingency.

Modes of Transmission of Cholera.

One of the most potent factors in the dissemination of cholera from place to place and country to country in times of peace, is the movement of crowds connected with commerce, labour, and religion. The great Hindu pilgrimages in India, and the great Mahommedan pilgrimages to Mecca and other sacred shrines, are active agents in the spread of cholera in epidemic form. Many Indian investigators have demonstrated their influence. Some of the exceptional festivals are attended by millions from nearly every part of India, but even the smaller ones are powerful in disseminating the disease, especially those held in the endemic area, such as at Calcutta and Puri. I remember the great outburst at the Ardhodoya Jog, in Calcutta, in 1891. It is a festival that occurs every 37 years. Cholera broke out at the festival and on the return journey of the pilgrims I was able to trace the spread of cholera from village to village through which the pilgrims had passed, and the setting up of local epidemics in the villages on the return of the pilgrims to their homes. No disease has had its extension from place to place so thoroughly traced to the lines of human intercourse as cholera. The influence of the Mahommedan pilgrims from different parts of the world to Mecca is well known. Mecca has played a part in most epidemics as a great disseminating centre. In 1883 I had the opportunity of demonstrating that two factors had played the chief rôle in the outbreak of cholera at Damietta, the first town attacked by cholera in Egypt in the epidemic of that year. One was the importation of the disease by pilgrims returning from the Hedjaz, and the other contamination of the river water from which the inhabitants drew their drinking water. The investigation merely confirmed the discovery of Snow in 1849 and 1854 as to the mode of spread in England and that it was applicable also to Egypt.

So much is known to-day regarding the transmission of cholera that it will hardly be realised that 30 years ago there were acute controversies on the subject.

[Professor Simpson then summarised the history of the cholera controversy from 1886, when Bryden's earth-borne and wind-disseminated theory was in the ascendant, and dwelt on Koch's confirmation in India of his discovery in Egypt of the comma bacillus. Referring to an investigation made by himself and Haffkine, he continued:]

In a paper at the Indian Medical Congress, held in Calcutta in 1894, we demonstrated that out of 46 tanks around which cholera existed, comma bacilli were found in 42, or 91·3 per cent.; and out of five tanks where cholera had disappeared a month to six weeks previously, comma bacilli were not found in any. This latter conformed to a common experience that if a tank was guarded for three weeks or a month, and further contamination with cholera dejecta prevented, the water was safe to drink. Of 15 wells examined, nine of which were in cholera-infected houses, comma bacilli were found in only one; other agencies were at work here. The air of infected rooms was examined and no commas found, even when the body of the deceased had not been removed and the floor of the hut had been soiled with cholera excreta. In a flour shop, a man attacked with diarrhœa had washed his clothes in a tank behind the premises, and we discovered his clothes still wet lying on a portion of flour exposed for sale. From the flour we obtained a culture of the comma bacillus. Cholera bacilli were also found in the surface drains inside infected houses and also in the drains leading to tanks.

But comma bacilli were not confined to the waters of the Hooghly or Tolly's Nullah, or the canal in the suburbs of Calcutta, or to tanks or drains. I had frequently observed a marked coincidence between outbreaks of cholera with diarrhœal disease among calves in the neighbourhood of tanks. This led us to examine cows and calves suffering from diarrhœa in the vicinity of cholera outbreaks, with the result that commas were found in the intestines of fatal cases, especially of calves. We also found comma bacilli in the cesspools connected with the cowsheds in which animals were suffering. The exact connexion of these commas to cholera in man we had no opportunity of determining. Further, in some fish examined by me, I found comma bacilli. Similar observations were subsequently made by Cunningham, Remlinger, and Nouri.

That flies can transport cholera bacilli, which become adherent to the surface of their bodies, was demonstrated by Grassi, Catani, Tizzoni, and Simmonds at an early period. The experiments of Samtchenko, in 1893, in the Kiew laboratory showed that cholera micro-organisms could live and multiply within the bodies of flies. Both observations suggested the possibility of contamination of food and the indirect spread of cholera by flies. In 1894 there was an outbreak of cholera in the Gaya jail, and Dr. Macrae, of the Indian Medical Service, traced it to the drinking of milk contaminated by flies from a neighbouring latrine. Haffkine isolated the comma bacillus from the milk.

Since the epidemic of 1892, at Hamburg, it has been frequently observed that persons who have been in contact with cholera patients, or living in infected localities, may have cholera bacilli in their intestinal discharges although they are perfectly well and never have had cholera. They are in the same position as persons who have been in contact with diphtheria and get lodged in their throats the diphtheria bacillus, which is harmless to them but dangerous to others. A certain percentage of those attacked with cholera become chronic carriers. Early observers have examined the bile of fatal cases and established the fact that the cholera bacillus in a certain percentage of cases is to be found in a pure culture in the bile. Major E. D. Greig, I.M.S., in 1913, confirmed these observations by investigations he was making at Puri during the pilgrim festival there. Out of 270 post-mortem examinations he found cholera vibrios in the gall-bladder in no fewer than 80 cases, and they were not only on the surface of the mucous membrane but also in the submucous tissue. This fact brings cholera into the same category as typhoid fever as regards the production of chronic cholera carriers. But cholera becomes even more closely allied to typhoid fever in its modes of dissemination when two very important facts, discovered and established by Major Greig, are taken into account. The first is that out of 55 cases of cholera he found the comma bacillus in the urine of eight of his patients, and in two of these cases the bacillus was recovered during the stage of convalescence, when the persons were going about their work. The other important fact is that he has found cholera bacilli in the lungs and other organs of some fatal cases of cholera.[2]

Preventive Measures and Anti-cholera Inoculations.

With cholera introduced into the war area, and its capability of spreading by carriers, by water, and by food or drink contaminated by infected stools or urine, by infected latrines and flies, contaminated boots, clothes, utensils, and hands, there is, when the season of the year and the condition of the population are favourable, a strong probability of much loss from this disease, and it is because of this probability that measures should at once be taken to prepare to combat this disease, and to protect the troops against cholera in Asia Minor, Egypt, and Europe.

It is obvious that disinfection of the latrines and the protection of water-supplies or purification of water are essential parts of any preventive measures. So are the isolation of the sick and the retention of convalescents until free of cholera bacilli in the fæces and urine. The disinfection of the latrines is necessary to prevent the contamination of flies which crowd to these latrines, and to prevent contamination of boots, &c. But as the conditions of warfare often render this difficult, if not impossible, and what may be done in our army may not be done in another, so that the one that takes precautions may suffer owing to neglect on the part of the other, it is important that the soldiers should be also protected by inoculation against cholera if that inoculation renders them less susceptible of being attacked by the disease.

There can be no doubt that the very extensive experiments with Haffkine's prophylactic against cholera, which were carried out in India on man and not on laboratory animals, 20 years ago, established the fact that these inoculations gave a very high protection against cholera attacks for at least one year. The experience gained in the cholera experiments was the guide to the preparation of the well-known Haffkine's prophylactic for plague, which has proved such a boon to communities attacked with plague. As most of the cholera vaccines—except those used in Upper India—were prepared in my laboratory at Calcutta, and as I had to collect the statistics relating not only to the experiments in Calcutta, for which I was responsible, but also with reference to the inoculations in different parts of India, in order to report on the subject, I can speak from experience as to their value. Haffkine and myself were ably seconded in the work by my medical assistants, more especially by Dr. R. Sen, Dr. Jogendra Nath Dutt, Dr. Sasi Bhusan Ghose, and Dr. J. J. Chowdry. The only disappointing result was connected with the first experiment, when, as a matter of caution, the soldiers of the East Lancashire Regiment were inoculated with only weak vaccine in small doses: after the lapse of 14 months from the time they were inoculated cholera of a very virulent character attacked the regiment, but even under the unfavourable conditions mentioned—viz., 14 months since the inoculation, the use of weak vaccines and small doses, and the type of the attacking cholera particularly virulent—the inoculated suffered to a less degree than the non-inoculated, thus: 640 non-inoculated soldiers had 120 cases (18·75 per cent.) with 79 deaths (12·34 per cent.); 123 inoculated soldiers had 18 cases (13·55 per cent.) with 13 deaths (9·77 per cent.).

As regards all the other experiments, whether among prisoners in jails, or coolies in camps or tea gardens, or among the general population in the bustees of Calcutta, the protection was of a most marked character. But it was observed that, as a general rule, the period of immunity did not last for more than 14 months. It would take too long to give you all the results recorded, but they are to be found in my annual report for 1896, and a much fuller account, with details, are given in Haffkine's paper on Protective Inoculation against Cholera, published in India in 1913. I shall give you those of Calcutta and of the Cachar tea-gardens.

7,690 persons were inoculated against cholera in 27 months, mostly in those bustees, or collection c huts, in which the poorer people lived, and which were usually visited by cholera year by year. Every effort was made by persuasion to get half the members of the hut inoculated. In some cases we were successful in this respect, in others not. We inoculated in the huts and then waited events. A complete register, with all details relating to each of the inoculated and the non-inoculated in the hut, was carefully kept, and when a case of cholera was reported investigations were immediately made. In the 27 months cholera visited 71 houses, in which inoculated and non-inoculated persons were living in the same households, and the following table shows the days on which cholera occurred among the non-inoculated and inoculated :—

Amongst the uninoculated members, after — 1, 2, 3, 4, 5,
and among the inoculated of the same households, after 0, — 2, 3, 4,

6, 9, 12, 13, 15, 17, 22, 34, 37, 44, 57, 62, 63, 71, 95, 99, 109,

114, 118, 119, 120, 129, 132, 139, 143, 162, 189, 191, 203, — 240,
219

251, 271, 281, 284, 300, 309, 318, 319, 334, 356, 359, 362, 370, 372,

378, 383, 384, 389, 391, 393, 394, 401, 404, 408, 416, — 433, 446,
421

459 512 688 735

and 738 days.
and 738 days.

During the first four days after the inoculation, cholera occurred among both the inoculated and non-inoculated, though in a smaller degree among the inoculated; after the first four days, there was a period of over a year when there was almost an absolute freedom among the inoculated, while among the non-inoculated in the same houses cases were occurring during the whole year; after 14 months cases began gradually to reappear among the inoculated as well as among the non-inoculated. Including the occurrences of cholera in the inoculated during the first four days the results for the whole period were as follows:—654 uninoculated individuals had 71 deaths (10·86 per cent.), while 412 inoculated in the same households had 12 deaths (2·99 per cent.).

---

[2] Indian Journal of Medical Research, vol. i., 1913.

The figures show that notwithstanding the incomplete protective effect of the first four days, and the gradual disappearance of the resistance in those inoculated with doses of weak vaccines only, which a number of the inoculated people received in the earlier days of the experiment, the mortality among the inoculated compared with that of the uninoculated was in the proportion of 1 to 3·63, giving a reduction of mortality of 72·47 per cent., or in other words, where inoculations were performed and which were subsequently visited by cholera there occurred for every 11 deaths amongst the uninoculated three deaths among a similar number of inoculated.

Even in regard to the first four days it was found that the mortality among the inoculated was 1·86 times smaller than among the non-inoculated, and that after that period the inoculated acquired a protection which, for a year at least, rendered them 22 times safer than the non-inoculated. In Haffkine's pamphlet on Protective Inoculation against Cholera, which covers a larger number of observations in Calcutta and a longer period—viz., 53 months instead of 27—he found that the number of deaths among the inoculated during the first our days was 1·39 times smaller than among the non-inoculated, and that during the period of mmunity lasting 412 days or 14 months, the number of deaths among the inoculated was 15·79 imes smaller than among the non-inoculated. It was also noticed that in bustees, where large numbers were inoculated, and which usually suffered rom cholera, there was in many instances an exceptional freedom from the disease.

Gradually, as more experience was gained, the attenuated vaccine—Vaccine No. I.—was given up and Vaccine No. II., the fixed and strong vaccine, was used instead. The latter was employed in the Durbhanga jail in April, 1896, during the progress of a very fatal epidemic. The prisoners were paraded, and every second man or woman was inoculated. The result was that after the inoculation, among a strength of 99 non-inoculated, there were 11 cases (11·11 per cent.), all fatal; while among 110 inoculated, there were 5 cases (4·55 per cent.), with 3 deaths (2·73 per cent.).

The strong vaccine was used on a large scale on coolies of the Cachar tea-gardens who, inoculated and uninoculated, lived together in the same huts. The results are recorded by Dr. Arthur Powell:—6549 uninoculated had 198 cases (3·02 per cent.) with 124 deaths (1·89 per cent.); 6778 inoculated had 27 cases (0·47 per cent.) with 14 deaths (0·24 per cent.).

The two vaccines with which the Indian experiments were made, and which established their protective value, consisted of live cultures. Vaccine II. was a strong vaccine fixed in strength by a process in the laboratory, into which I need not enter, but which is frequently erroneously called Kolle's method by those who are not familiar with the fundamental experiments made by Haffkine in India. Vaccine I. was an attenuated preparation of Vaccine II.

Experience with the inoculations indicated that the weak vaccine was not so protective as the strong, and that the strong vaccine, though it caused, when inoculated into a guinea-pig without a preliminary inoculation of the weak vaccine, a necrotic swelling produced no such effect on man. In fact, the experiments on man brushed aside many of the theories and deductions formed from similar experiment on laboratory animals. Another experience was that it is not safe to rely on the vaccine giving protection for more than 14 months, and, lastly, that though the weak and strong vaccine protected against attacks of cholera, they had not the same protective effect against death as the two strong vaccines when an inoculated person was attacked with the disease. It was because of the experience gained with the cholera vaccine that a different mode of preparation of the vaccine against plague was adopted and because plague is a septicæmic disease the vaccine was devitalised. The value of the chemical product thus prepared and used as a prophylactic for plague, both in protecting against attacks of plague and reducing the chances of death when attacked, has been well established. In cholera some devitalised preparations of vaccines were used in India, but no opportunity was offered for testing their efficiency. It was the live cultures that were used, and it is generally agreed that they are more efficient than dead cultures. Haffkine holds the view that similar experiments are needed to test the value of the devitalised vaccines of cholera, as those which were employed to ascertain the efficacy of the live vaccines of cholera and the devitalised vaccine of plague.

There can be no doubt that devitalised vaccines, if efficient, are the best for administration on a large scale, and although there has been no scientific proof of their efficiency, based on researches on man, such as have established the value of the living vaccines of cholera and the devitalised vaccines of plague and typhoid fever, yet there are occasions on which they have been used in which evidence of a general character has indicated that they also are of great value and similar in character to those of typhoid and plague. When visiting Kitasato's laboratory in Japan in 1902, I found the devitalised cultures of Vaccine II. were being used with what was believed to be satisfactory results. Over 70,000 people were inoculated with this vaccine. Castellani has used the devitalised vaccines in Ceylon since 1905, combined with those of typhoid fever and paratyphoid A and B in one mixture.[3] This is a combination which saves and eliminates an unnecessary number of inoculations and which at the same time does not produce any antagonistic effect. The devitalised preparations were employed in Petrograd in 1908 and 1909 and in Batavia in 1910 and 1911, over 30,000 people being inoculated in each of these towns. Similarly the devitalised preparations were employed on a large scale by the Greeks during their military operations in Macedonia in 1913. The appearance of the first cases of cholera at Chataldja in the Turkish army, and later in the Bulgarian army, decided the Greek authorities to begin a general vaccination of the army and of the civil population of that part of

---

[3] Brit. Med. Jour., Nov. 7th, 1914.

Macedonia occupied by the Greek army. For this purpose two anti-cholera ambulances were attached to each division of the army. One was a rapidly travelling section containing a well-equipped laboratory and disinfecting stove, under the direction of a medical bacteriologist, and the other a stationary section, under the direction of a medical man, equipped with material necessary for transport and treatment of 25 cholera patients. Some 50 bacteriologists were employed, of whom 35 were civil and 15 military, and the inoculations were performed by the regimental medical officers and the civilian doctors in different localities, who were supplied with material and printed instructions. The organisation and administration of the anti-cholera campaign, both in the army and civil population, was placed in the hands of Professor C. Savas working in conjunction with M. Manoussos, the principal medical officer of the army. Professor Savas gives in the *Bulletin of the Office International d'Hygiène Publique*, of October, 1914, a very full account of the measures taken to carry out anti-cholera inoculations in the army and civil population in the infected area, and the effect they had in checking and suppressing the epidemic.

Approximately half a million persons were inoculated. This included about 150,000 soldiers, 350,000 civilians and refugees in Macedonia, and about 150,000 civilians and refugees in Salonika. In ten divisions, consisting of 114,803 soldiers, which took part in the Græco-Bulgarian War, there were only 2192 cases of cholera (19 per 1000). The incidence on inoculated and not inoculated was as follows:—

2 vaccinations.	91,224 soldiers	had 644 cases	= 7	per 1000.
1 vaccination.	14,613 ,,	,, 618 ,,	= 42	,,
Not vaccinated	8,968 ,,	,, 634 ,,	= 93	,,

Those vaccinated only once had six times more cholera cases than those vaccinated twice, and those not vaccinated had 14 times more. If to the non-vaccinated be added 96 fulminating cases which are stated to have occurred among them, the ratio rises to 103 per 1000.

It was reported by the principal medical officers of divisions that as soon as the vaccination of these were finished, cholera disappeared as by enchantment, and only remained sporadic among soldiers sent to fill up vacancies, and who had not been vaccinated, and this though the soldiers remained in localities where cholera was prevailing amongst the civil population and the refugees.

Further, in the first division, specially in which the first cases of cholera occurred, and in which the double vaccination had been completed before hostilities commenced, there were only a few cases of cholera reported, and only among soldiers who had been sent from Athens and had not been vaccinated, whilst the other divisions which coöperated with them were attacked by the epidemic.

It was noticed, also, that in the towns and villages a double vaccination of the inhabitants was followed by a sudden decrease and prompt disappearance of the epidemic, and it is to these vaccinations that Professor Savas ascribes the control and suppression of the disease, both in the army and among the civil population of the infected towns, and the protection of Greece from the ravages of cholera when the population was under conditions where other sanitary precautions were difficult or impossible to adopt.

The success attending these inoculations is similar to that which I have had in regard to plague. In 1913 the whole population of Mombassa, resident and floating, was inoculated during an epidemic of plague, with the result that the disease was effectually stamped out. I had a similar experience in 1908 in West Africa. In both localities pneumonic, as well as bubonic, plague prevailed. The inoculations were, of course, combined with all other known methods of combating the disease.

Professor Savas attributes to the inoculations the saving of Greece from a serious epidemic; concludes that 99 per cent. of persons inoculated twice remained refractory to the epidemic; and classes anti-cholera inoculations among the most efficacious preventatives against cholera.

While recognising the extraordinary good effect which the inoculations had in checking and suppressing cholera in this particular campaign there is one important point which has to be remembered in order to gauge the power of the inoculations at their true value, and that is that the type of cholera was not of a virulent character except in the 96 fulminating cases among the non-inoculated. The vaccines were capable of dealing with the epidemic, but it was a comparatively mild epidemic that was dealt with.

There is much variancy in the virulence of epidemics of cholera. I have seen an epidemic in which the mortality was as high as between 80 and 90 per cent., and I have seen others which have had a mortality of less than 20 per cent. It is important in preparing vaccines against an epidemic to obtain for the inoculations a natural strain of cholera bacillus from as virulent a type of cholera as possible, in order that the immunising effect shall be well above the type of the epidemic, and in order that it can be maintained with ease at a high and fixed state of virulence in the laboratory. Whether the present Russian strain will be the most effective to combat any natural exaltation of epidemics due to recrudescences or importation under the conditions mentioned, may well be a matter of doubt, seeing that since 1911 its virulence and capacity to spread have been diminishing.

I think Castellani's method of mixing the vaccine is well worth consideration as being practical and convenient. It is not doing anything different from inoculating on one arm with typhoid vaccine and vaccinating on the other at the same time against small-pox.

SOME CASES OF BLOOD INFECTION B AN ANAEROBIC ORGANISM SECONDARY TO WOUNDS.

BY ADRIAN STOKES, M.D.DUB., F.R.C.S.IREL.,
LIEUTENANT, R.A.M.C. (TEMP.).

DURING the months of October, November December, and January, while doing bacteriological work in connexion with the clearing hospitals, a series of cases in wounded men occurred giving the same clinical and bacteriological picture. The clinical picture was characterised by four separate features: (1) the colour of the patient, which was a dirty yellow, something like the colour of a dirt deal table; (2) the soft, running pulse, which was always very rapid, often uncountable, and i the later stages irregular; (3) uncontrollable vomiting; and (4) the rapid onset of the condition after the injury. The presence of obvious gangrene at the site of the wound was inconstant; in three of the six cases reported it was present, in the remaining three it was absent. Death occurred in every case with great rapidity, 48 hours being the average time; one case survived 80 hours. The patient was always conscious to the end and in a state of "euphoria."

It appeared probable from the great similarity of the symptoms and the invariable result in every case that there might be a common cause. The presence of the bacillus of malignant œdema was suggested as the probable explanation. An attempt to isolate the organism from the wounds having failed in two cases, it was thought that it might be found in the blood stream, and accordingly blood cultures were made in the series of cases reported. In six cases a culture was obtained by this method of an organism which was indistinguishable from the bacillus aerogenes capsulatus. The blood cultures were made in three cases immediately after death from the heart's blood, and in the three remaining cases the blood cultures were ante mortem. Two patients died after a week in hospital from typical gas gangrene; the culture was negative in one case ante mortem and in the other post mortem. The former case had been twice operated on in attempting to stay the spread of the gangrene; in the latter it was thought that the patient would not stand re-amputation—in this case the culture was ante mortem, and gave a positive culture of staphylococcus aureus. These two cases seem to make it probable that the series in which positive cultures of an anaerobic organism were obtained may be a separate and distinct condition. The number of cases in which it was possible to verify the diagnosis of blood infection by culture is small; on the other hand, there were no negative cultures in cases which were regarded as typical of the condition. The six cases in which blood cultures were positive were as follows:—

Case.	No. of c.c.	Place.	Hours of survival after wound.	Time of blood culture.	Projectile.	Wound.
1	4	Braisne.	50	P.M.	Shell.	Compound, femur.
2	4	Poperinghe.	40	P.M.	Shell.	Compound, femur.
3	4	Poperinghe.	60	P.M.	Bullet.	Compound, humerus.
4	4	Lillers.	48	A.M.	Shell.	Compound, humerus and femur.
5	1	Béthune.	80	A.M.	Bomb.	Arm, no fracture.
6	4	Lillers.	40	A.M.	Shell.	Compound, femur.

The technique adopted was the same in all the cases. Shake cultures in glucose-agar were made as soon as possible after the blood was taken; at the same time ordinary aerobic blood plates were made which in every case were negative at the end of 48 hours. In the shake cultures bubbles of gas were observed in all the cultures on the next day. In five of the positive cultures gas appeared with great rapidity, in two it was apparent in six hours, and in three it appeared in ten hours. The culture was profuse and the formation of gas abundant, the agar being forced to the top of the tube. Growth ceased within an inch of the surface of the medium and seemed most active about two inches from the surface. The organism was a Gram-positive bacillus, most of the bacilli taking the Gram stain well, a few individuals losing the stain, and a few showing a beaded appearance. The bacilli varied a good deal in length, forms longer than anthrax being common and forms as short as B. coli were found; it did not form spores in glucose-agar and died out in one week in that medium. In one culture (Case 4) capsules were stained; in the others they were apparently present, but it was not possible to stain the actual capsule. The colonies were dense and opaque, and on McLeod's plates made with blood-glucose-agar they showed a distinct hæmolytic power. The organism is non-motile. It was possible by making use of the hæmolysis to isolate the same microbe from two quite harmless wounds, one in the leg, the second in the thigh. One culture (Case 4) killed a guinea-pig in 15 hours; another culture (Case 5) made a pig very ill, but it did not die; these were the only cultures injected into animals. There were a large number of cases presenting the same clinical picture in which it was not possible to do blood cultures to verify the diagnosis.

From the very rapid onset of the symptoms it is probable that the infection of the blood stream is either at the time of injury or very soon after it.

NOTE ON A CASE SHOWING

THE FREQUENT OCCURRENCE OF AN AURICULO-VENTRICULAR RHYTHM ASSOCIATED WITH A LONG A-C INTERVAL.

By A. W. FALCONER, M.D. ABERD., M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, ABERDEEN ROYAL INFIRMARY.

IN describing the following case I shall assume it to be proved that under normal conditions the heart beats in response to a stimulus formed in the sino-auricular node, and shall refer to this rhythm as the S.-A. rhythm. I also shall assume it to be proved that, under certain conditions, the seat of the impulse formation in the mammalian heart may temporarily or permanently shift from its normal site in the sino-auricular node to some other portion of the heart, more particularly to parts containing specialised tissue of the same nature as the sino-auricular node.

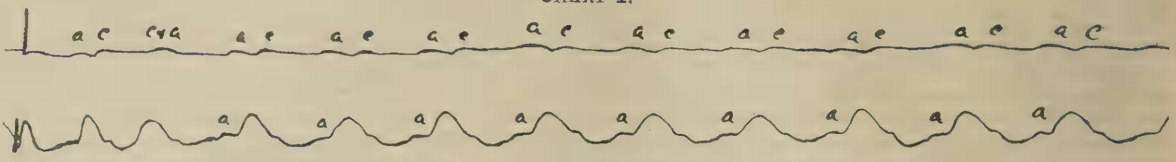
In addition to the sino-auricular node the chief mass of this specialised tissue is the auriculo-ventricular node of Tawara and the bundle of His. Since the discovery of this tissue in the mammalian heart a large amount of experimental work has been carried out by Engelmann, Lohmann, Hering, Rothberger and Winterberg, Ganter and Zahn, Kuré, Meek and Eyster, Lewis, and others on the relations existing between the sino-auricular and auriculo-ventricular nodes.

These investigators have shown that procedures which depress, injure, or extirpate the sino-auricular node, such as cooling, cutting, clamping, burning, and poisoning with certain drugs such as formalin, bring on a condition in which the normal interval between auricular and ventricular contraction becomes markedly shortened or even negative, the contraction of the auricle following, instead of preceding, the ventricular contraction. An exactly similar condition is produced by procedures which stimulate the auriculo-ventricular junction such as left accelerator stimulation.

Most authorities are now agreed that in these circumstances the sino-auricular node has ceased to act as the pace-maker of the heart, and that the auricles and ventricles then respond to a rhythmical stimulus originating in some part of the auriculo-ventricular node, which stimulus throws the auricles and ventricles into more or less simultaneous contraction. I shall refer to this rhythm as the auriculo-ventricular rhythm.

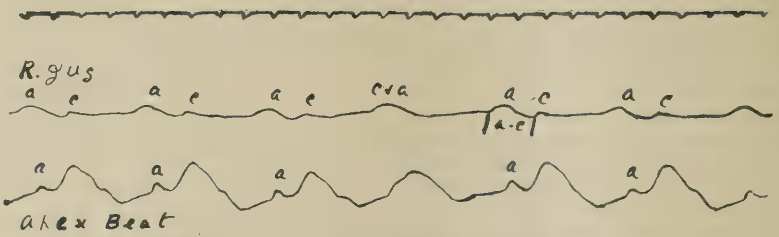
The following case was admitted into the Aberdeen Royal Infirmary on April 7th, 1914, under Professor A. W. Mackintosh, to whom I am indebted for permission to publish it.

CHART 1.



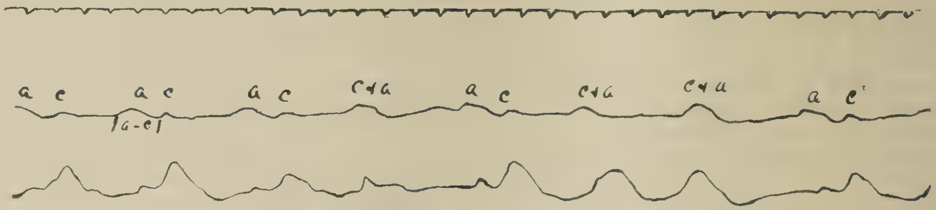
Upper tracing: jugular pulse. Lower tracing: apex beat. Note extrasystole ($c + a$) at second cycle.

CHART 2.



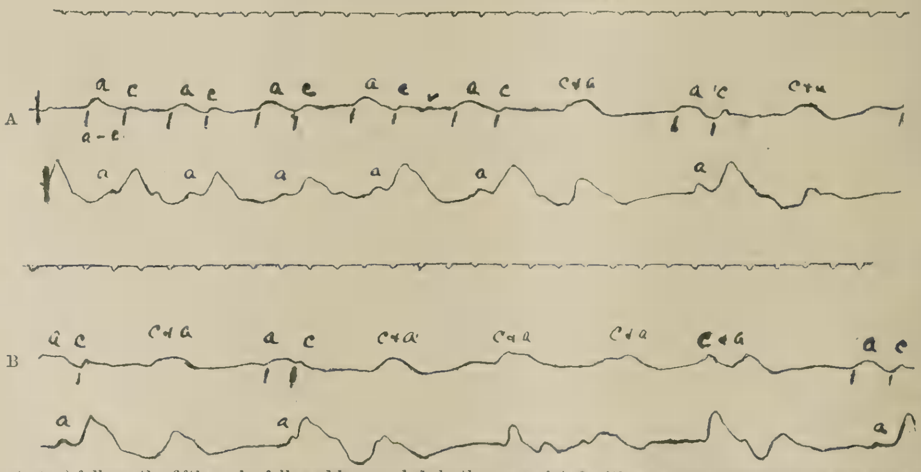
Same rhythm, with extrasystole ($c + a$) at fourth cycle.

CHART 3.



Note the two extrasystoles ($c + a$) following one another.

CHART 4, A AND B (*continuous*).



Extrasystole ($c + a$) follows the fifth cycle, followed by coupled rhythm, associated with a gradual diminution in the a-c interval until in the fifth and sixth couples the auricles and ventricles contract simultaneously, the a-c interval reappears at the seventh couple.

The patient was a male, aged 33, a labourer. He stated that he had never had rheumatism, but had suffered from some form of venereal disease in 1905. Up to three weeks before admission to hospital he had felt quite well and able to do his work without any discomfort. He then began to suffer from pain over the epigastrium. This pain was brought on by exertion and diminished by rest. About the same time he also began to be troubled with severe breathlessness on exertion, and a fortnight before admission to hospital he had to give up work on account of severe dyspnœa, which was brought on by the slightest exertion.

On admission to hospital the patient was able to lie quite comfortably in bed. There was no œdema and the urine was free from albumin. The liver was not demonstrably enlarged. The Wassermann reaction was strongly positive in the blood. The apex beat of the heart was in the fifth intercostal space, one inch outside the nipple line. There was a mitral systolic murmur and the sounds over the aortic and pulmonary areas were almost inaudible.

The heart's action presented several interesting irregularities. On the day after admission the heart-rate was 150 per minute and a polygraphic tracing showed a coupled rhythm. Each normal heart beat was followed by an extrasystole with a compensatory pause. The *a-c* interval was just one-fifth of a second. During the extrasystole there was only one wave in the jugular tracing which was synchronous with the wave in the carotid tracing. This wave was larger than the *c* waves of the normal cardiac cycles and suggested that the auricles and ventricles were in simultaneous contraction. The patient was put on ʒi of tincture of digitalis daily, and this was continued for eight days. After ʒii of the digitalis the pulse-rate fell to 75 per minute, and apart from an occasional extrasystole the pulse became regular for considerable periods. Chart 1 is an example of this rhythm. Except for an extrasystole occurring at the second cycle the heart's action is perfectly regular. The jugular pulse shows well-marked *a* and *c* waves corresponding to each cardiac cycle. The *a-c* interval is prolonged. The apex-beat tracing shows an unusually well-marked *a* wave preceding the ventricular rise. Chart 2 shows the same rhythm with the occurrence of an extrasystole at the fourth cycle. The *a-c* interval is definitely prolonged. The extrasystole is fully compensatory and the jugular tracing shows only a single wave *c* synchronous with the ventricular rise in the apex-beat tracing. This *c* wave, however, appears at exactly the moment when a normal auricular contraction is due, and from a polygraphic tracing alone it is impossible to say whether the simultaneous contraction of auricles and ventricles is due to a ventricular or an auriculo-ventricular extrasystole. Occasionally two such extrasystoles followed one another, as seen in Chart 3.

In addition to these extrasystoles the heart's action showed the frequent occurrence of the irregularity seen in Chart 4, A and B. In this tracing the first five cycles show, both in the jugular and apex-beat tracings, auricular and ventricular waves with a prolonged *a-c* interval. Following the fifth cycle is an extrasystole of the same type as in Charts 2 and 3. From here onwards we have a coupled rhythm with a gradual diminution in the *a-c* interval of the first beat of the couple till in the fifth and sixth couples the *a-c* interval has completely disappeared, and the auricles and ventricles are contracting simultaneously. At the seventh couple the *a-c* interval again appears. This peculiar rhythm frequently appeared during the patient's stay in hospital, and always presented the same features.

This gradual disappearance of the *a-c* interval can only be attributed to a temporary change in the site of the pace-maker of the heart from the sinus node to some part of the A.-V. node or bundle, probably the result of an irritative lesion in that neighbourhood. As corroborative evidence we have the presence of extrasystoles and a prolonged *a-c* interval. The fact that in the experimental production of an A.-V. rhythm the *a-c* interval shows a gradual shortening and not an abrupt disappearance has been demonstrated by Hering and others. It has been suggested that this gradual change depends either on a gradual shifting or wandering downwards of the pace-maker or to changes in conduction time.

Aberdeen.

A CASE OF ACHOLURIC JAUNDICE.

BY W. HARMENS, M.B., B.C. CANTAB.

THE following case presents several points of interest both as regards diagnosis and treatment.

The patient is a married woman, aged 27, who has two children, both girls, aged 5½ and 2½ years respectively. In neither is there any enlargement of the spleen. Her maternal grandmother died in rather early life from a "floating tumour" in the abdomen. Her mother died seven years ago from "hæmorrhage," having been in bed a month. Splenic enlargement had been noticed 16 years before her death. During that time she had much ill-health with repeated attacks of jaundice. She was always more or less "yellow." When the patient was 16 years old a swelling was noticed in her left side. Jaundice appeared for the first time 18 months ago, and she lost considerably in weight. She complained of inability to do her work properly, loss of appetite, and feeling generally ill. A considerable amount of pain was present in the left side of a dragging nature, but it was never acute. She was sent to St. Thomas's Hospital about 18 months ago with the diagnosis "splenic enlargement." There she gradually improved under treatment. The spleen extended to a point at the level of the umbilicus. The liver was also slightly enlarged. A moderate degree of anæmia was present. Her blood count at that time was: red cells, 3,000,000; white cells, 9200. An X ray examination was made but was negative.

In the beginning of May, 1914, the same symptoms reappeared. A slight degree of jaundice developed, which gradually became deeper but was never intense. The pain in the left side was nearly always present and often severe, and prevented her carrying on her household duties. She looked pale and anæmic, and said she had lost flesh. There was marked enlargement of the spleen, which extended to a point half an inch below a horizontal line drawn through the umbilicus. No tenderness was present. The liver was slightly enlarged, and extended from the sixth rib above to a point three-quarters of an inch below the costal margin. Hæmic murmurs were present over the heart. The urine was very dark in colour, acid in reaction, of specific gravity 1024, and contained no albumin or sugar. Bile pigment was not present. There were no signs of disease elsewhere. In view of her symptoms I sent her to St. Thomas's Hospital, where she was admitted under Dr. H. G. Turney. On July 9th a differential blood count was made by Dr. L. S. Dudgeon as follows: Erythrocytes, 4,000,000; slight poikilocytosis present; rouleaux formation fair; fibrin formation fair. Hæmoglobin, 90 per cent. Colour index, 1·1. Leucocytes, 10,240; polynuclear neutrophiles, 64·25 per cent.; polynuclear eosinophiles, 2·25 per cent.; small lymphocytes, 25·75 per cent.; large lymphocytes, 3·50 per cent.; large hyaline, 3·25 per cent.; coarsely granular basophiles, 1·00 per cent. No nucleated red cells were seen. The coagulation-time was normal. The fragility of the red cells, tested by sodium chloride in distilled water, was very markedly increased as in congenital cholæmia.

0·8%	... ,, ...	,,

A Wassermann reaction was done but was negative. While in hospital the temperature was slightly raised, 100·2° F. being the highest recorded. The mean was about 99·4°.

For reasons which will presently be discussed it was decided to remove the spleen. The operation was performed on July 27th by Mr. H. Betham Robinson. The anæsthetic used was chloroform and ether. The peritoneum was found to be adherent in many places. The patient stood the operation well, and had the stitches removed on the seventh day. On August 5th another examination of the blood was made as follows:—Erythrocytes, 3,612,500; rouleaux formation good; fibrin formation good. Hæmoglobin, 75 per cent. Colour index, 1. Leucocytes, 7800; polynuclear neutrophiles, 42·75 per cent.; polynuclear eosinophiles, 2·75 per cent.; small lymphocytes, 32·00 per cent.; large lymphocytes, 9·00 per cent.; large hyaline, 12·00 per cent.; and coarsely granular basophiles, 1·5 per cent. On August 12th, the day of her discharge from hospital, the fragility of the red cells was much less than at the previous examination.

0·35 ,,	,,
0·52 ,,	Faint trace.
0·55 ,,	No hæmolysis.
0·6 ,,	,,

The patient's weight on admission was 7 st. 6 lb. and on her discharge 7 st. 12½ lb. Her colour had greatly improved, and her appetite was good. On Oct. 1st the fragility of the red cells was again tested and was found to be practically normal.

NaCl in distilled water.	
0·38 per cent.	Complete hæmolysis.
0·52 ,,	Trace.
0·6 ,,	No hæmolysis.

For a time after the operation the patient had a slight limp and a dragging pain in the left side. These symptoms have completely disappeared, and she says she feels perfectly well. She is able to carry out her household duties and look after her husband and children. She is delighted with the change in herself since the operation.

Two clinical groups of acholuric jaundice may be recognised: in the one the condition is congenital and hereditary or familial, in the other acquired and lacking the hereditary tendency. In other respects the course and symptoms of the two groups are identical. The case just described seems to be a compromise between the two types. On the one hand the hereditary tendency is very marked, while on the other there was no appearance of symptoms till about the time of puberty. Of course it is possible, as there was never anything like persistent jaundice, that the case was really congenital but latent.

With regard to the indication for operation, it must be granted that the mere diagnosis of acholuric jaundice is not in itself sufficient. The condition, whether congenital or acquired, is compatible with many years of healthy life. In this patient the impairment of general health was very considerable. Abdominal pains were more or less persistent. They were due probably to the dragging of the splenic tumour so far as the more chronic ones were concerned, but in addition to these there were others of a different type and of a different distribution which occurred synchronously with the attacks of jaundice, and were dependent to all seeming upon changes in the gall-bladder and ducts. These symptoms in themselves afforded sufficient justification for the removal of the spleen, especially as the organ was of moderate size and its extirpation promised to be attended with the minimum of risk. But in addition to these actual inconveniences from which the patient might be promised relief there were others looming in the future which could not be ignored. The mother died from hæmatemesis 16 years after the enlargement of the spleen was diagnosed, and there is no ground for suspecting in her case either alcoholic excess or the presence of a gastric ulcer. It is quite certain that the exaggerated hæmolysis which is the underlying condition of acholuric jaundice must throw an enormous increase of work upon the liver, and there is clinical evidence of this in the enlargement of that organ. Eppinger has shown that even during apparently quiescent periods of acholuric jaundice the excretion of urobilinogen may be increased ten- or even twenty-fold, and increase of function to this extent must surely entail some danger of structural change in the long run in the organs concerned. The history of the mother's illness is, to say the least, suggestive of the same sequence of pathological events that we find in Banti's disease, and in both mother and daughter we find the same history of repeated attacks of jaundice with enlargement of spleen. So far as I am aware, the only change hitherto described as occurring in the liver in these cases is the accumulation of pigment-bearing cells without cirrhosis, but pathological evidence of any sort is far too scanty for a final verdict.

I wish to acknowledge the great kindness of Dr. Turney in the help he has given me, and to thank both him and Dr. Dudgeon for the use of the notes on the case.

Addlestone, Surrey.

CEREBRO-SPINAL MENINGITIS: MENINGOCOCCI FOUND IN PERIPHERAL BLOOD FILMS.

BY ALFRED C. COLES, M.D., D.Sc., F.R.S. EDIN., M.R.C.P. LOND.,

PHYSICIAN TO THE ROYAL NATIONAL SANATORIUM, BOURNEMOUTH.

Dr. A. D. Edwards, medical officer of health of Bournemouth, has given me the following notes of this septicæmic type of case of cerebro-spinal meningitis.

The patient, a male aged 33, a carpenter, was at work on the morning of March 15th, when he complained of pains in the lower part of the back, felt shivery, and soon afterwards vomited. After this sudden onset the patient became rapidly worse, and by the evening he complained of "aching all over." A purpuric rash appeared on the following morning on the brow and face. Retraction of the head was not present at this or any other stage of the illness. Dr. Edwards saw the patient for the first time on the afternoon of March 16th when his temperature was normal, but the pulse could not be felt. There was a well-marked purpuric rash on the face consisting mainly of more or less circular spots, dark purple in colour. There was also extravasation of blood on the trunk, especially on the buttocks. The patient was conscious and complained of "pains all over," so that he could not rest easily in bed. Pains in the knees and elbows were marked, especially on movement; for this reason Kernig's sign was not available. On lumbar puncture 25 c.c. of cerebro-spinal fluid were removed, and antimeningococcic serum was injected to the same quantity. The fluid came out slowly; it was mixed with blood, but otherwise was not very turbid. No growth occurred on blood serum or on agar, although there was blood in the inoculating fluid. The patient's temperature rose on the night of March 16th to 102° F., but fell on the morning of the 17th. There was diarrhœa on the night of March 16th, and the vomiting which had been occasional became frequent on the morning of the 17th. During that morning the patient became comatose and died on the afternoon of the 17th, 50 hours after the onset of the first symptom.

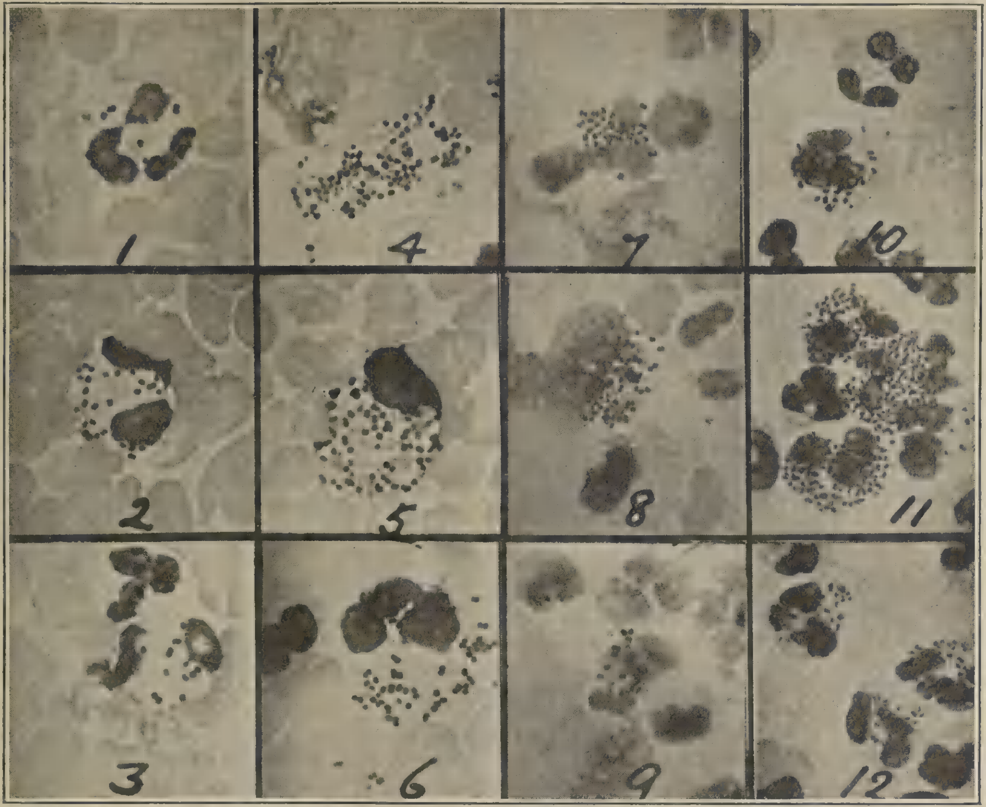
Clinically the case appeared to be a picture of profound septicæmia; there were no signs or symptoms to indicate the presence of meningitis. This latter condition was suspected mainly by the process of exclusion, and because the epidemic disease was known to be prevalent in certain military centres at the present time.

On March 17th, at 11.30 A.M., I made films from the blood obtained by puncturing the ear and procured about 20 c.c. of spinal fluid which had been drawn off on the previous day. The latter had a very slight deposit, which appeared to the naked eye to be almost entirely blood. On microscopic examination it was found to consist of red corpuscles with a few white cells, but no meningococci could be detected.

The blood films made from the blood of the ear were stained by Giemsa's method, and showed a moderate leucocytosis of about 12,000 to 13,000. A differential count showed the following percentage of leucocytes: Polymorphs, 80; large mononuclears, 19; lymphocytes, 1; eosinophiles, 0; in other words, the leucocytes were almost entirely polymorphonuclear, transitional, or large mononuclear types, many of which were vacuolated.

Whilst counting 2000 leucocytes, 10 were found to contain typical meningococci. Under a low power (8 mm. objective and compensating ocular 6) these appeared very much like deeply stained blue granules lying in the protoplasm of the cell, and when examined under the immersion lens they were found to be typical bean-shaped diplococci indistinguishable from gonococci. (I have carefully compared the meningococcus, or, to give it its full name, diplococcus intracellularis meningitidis (Weichselbaum), as found in the peripheral blood or in the cerebro-spinal fluid, with the gonococcus in urethral pus under a magnification of 3000 diameters, and I must confess that I can find no morphological difference. Both show considerable variations in size, but possibly the latter organism more frequently appears to lie in a capsule or vacuole.) The number of organisms lying in the protoplasm varied; in some cases there were only one or two pairs, in other cases the protoplasm was filled, but on an average there were about six in an infected leucocyte. (See microphotographs.)

With Giemsa's stain the meningococci stain a deep blue colour, but when there are many organisms lying in the protoplasm it is interesting to note that whilst the majority take the basic stain and appear blue, a certain number of them are faintly stained with the eosine and appear as very indistinct pale-pink bodies, but they still retain their typical bean-shaped character. Free diplococci were seen but they were infrequent, though occasionally a group consisting of several organisms was found.



Microphotographs of Meningococci and Gonococci. × 1000 diameters.

FIGS. 1 to 6.—Meningococci from peripheral blood showing variations in the number of organisms in the leucocyte. FIG. 4, free meningococci.
FIGS. 7, 8, 9.—Meningococci from cerebro-spinal fluid of another case of cerebro-spinal meningitis.
FIGS. 10, 11, 12.—Gonococci from urethral pus, showing the close resemblance of these organisms to meningococci.

The discovery of a comparatively large number of meningococci in films made from the peripheral blood suggests, to my mind, the following questions:—

1. As the cultivation of the meningococcus is a difficult and not very successful means of recognising the disease (Eisler has only obtained positive cultures from the blood in 10 out of 41 cases), are the organisms to be commonly found in films made from the peripheral blood in cases of cerebro-spinal fever, and is this a practical method of diagnosis, or are the meningococci only to be found in the septicæmic type of the disease?

2. As the meningococcus may occur in large numbers in the peripheral circulation, and as it is a very delicate short-lived organism very susceptible to drying, may not the disease be

conveyed by some blood-sucking insect? Dr. Edwards tells me that one of his very rapidly fatal cases complained of having been bitten on the back of the neck by a body louse a short time before his illness, *post* or *propter hoc*.

I would like to acknowledge my indebtedness to Dr. Edwards for permission to examine this case, for the clinical notes he has kindly supplied, and for his interest in my results.

Bournemouth.

INJECTION OF OXYGEN AS A TREATMENT FOR TETANUS.

BY H. O. HOWITT, M.D., L.R.C.P. LOND., M.R.C.S. ENG.,
AND
D. H. JONES,
PROFESSOR OF BACTERIOLOGY, ONTARIO AGRICULTURAL COLLEGE, GUELPH, CANADA.

As B. tetani is an obligate anaerobe and will not develop in the presence of the smallest amount of oxygen, it was thought that the injection of oxygen into a tetanus wound, and into the tissue immediately surrounding the wound, would be more or less efficacious as a treatment, or auxiliary treatment, in delaying the onset of the disease or rendering it less acute, if not in preventing the development of the disease altogether.

In the *Canadian Medical Association Journal* for November, 1914, one of us (H. O. H.) reported beneficial results from the subcutaneous injection of oxygen in cases of dyspnœa of tuberculosis, gas poisoning, pneumonia, œdema of lungs, bronchial asthma, and operative cases, and the success with this treatment led to the surmise that it might be valuable in cases of tetanus and other anaerobic infections, such as malignant œdema, symptomatic anthrax, &c. The prevalence of tetanus infections, causing extreme mortality in the European war zone, made it appear probable that a few animal inoculation experiments with tetanus and the subcutaneous injection of oxygen might be of use in ascertaining whether the treatment was of any value in this connexion. Accordingly, Dr. G. C. Creelman, president of the Ontario Agricultural College, was asked if it would be possible to carry on the experiments with tetanus in the bacteriological laboratory of the College. Dr. Creelman readily gave his consent and referred the matter to one of us (D. H. J.) in charge of the laboratory. As a result, the following experiments were planned, in which we were respectively responsible for the oxygen injections and the cultures, inoculations, and subsequent observations.

Cultures used.—A fresh culture of B. tetani was obtained from the Parke Davis Co., and subcultures were made from this in dextrose beef-extract bouillon and dextrose beef-extract agar, incubated under anaerobic conditions at 37° C. for three days, and kept later at room temperature.

Virulence tests.—To test the virulence of the cultures a guinea-pig, weighing 790 grammes, was inoculated subcutaneously on the inner side of the right thigh with two drops of a three-day old bouillon culture. After 24 hours tetanic symptoms were shown by the extension backwards and outwards in a rigid condition of the inoculated leg. Five hours later respiration was laboured, and the hinder half of the body was partially paralysed, being dragged around the cage with difficulty; 12 hours later—a total of 41 hours from the time of inoculation—the animal was found dead.

Oxygen injection experiments.—The oxygen injected was obtained from some oxone cartridges as prepared by the Roessler and Hasslacher Chem. Co., New York, from which oxygen was generated in the portable oxygen generator made by the Hartz Company, of Toronto, Cleveland, and Detroit. The oxygen escapes by means of a long rubber tube, at the distal end of which is an aspirating needle which is inserted into the subcutaneous tissue. The tube is then oiled, and by a pumping action of the hand the oxygen is forced through the needle.

Series I.

In this series four guinea-pigs were used. They were divided into two pairs. All four were inoculated with B. tetani, and one member of each pair was given an injection of oxygen near the point of inoculation, while the remaining member of each pair was kept as a control. Sufficient oxygen was given to raise an emphysema from 3 to 5 centimetres in diameter in the immediate region of the point of inoculation. (*Note.*—In all the cases where tetanus developed the symptoms were similar to those described above in the virulence test, the only difference being the varying time of onset and termination of the disease.)

Pair 1, Guinea-pig 1 (*760 grammes—control*).—Inoculated subcutaneously with half a drop of an eight-day bouillon culture on inner side of right thigh. Result: Tetanic symptoms first observed after 36 hours. Convulsions and death after 72 hours.

Guinea-pig 2 (*760 grammes*).—Inoculated same as No. 1, but oxygen injected immediately after. Result: After 18 days no tetanic symptoms had developed; guinea-pig well, having shown but little inconvenience at any time.

Guinea-pig 3 (*840 grammes—control*).—Inoculated with one drop of eight-day bouillon culture. Result: Tetanic symptoms first observed after 30 hours. Convulsions and death after 46 hours.

Guinea-pig 4 (*720 grammes*).—Inoculated as above and given injection of oxygen immediately. Result: Tetanic symptoms first observed after 44 hours. Convulsions and death after 84 hours.

We see from the above that with the first pair of guinea-pigs where half a drop of culture was used for inoculation tetanus developed and terminated fatally in the case of the control, but had not developed where oxygen was injected 18 days later. With the second pair, where the amount of inoculum was double that used with the first pair, tetanus developed with fatal termination in both cases, but the appearance of tetanic symptoms and subsequent death were considerably deferred by the one injection of oxygen.

Series II.

For this series the agar-plate cultures were used. To inoculate, a puncture was made through the skin with a sterile sharp instrument, then a platinum needle was drawn through the surface growth of the culture and inserted into the wound. As with Series I., four guinea-pigs were used. They were divided into pairs, and one of each pair was inoculated and immediately given a subcutaneous injection of oxygen, and the other member of each pair was inoculated and not given oxygen.

Pair 1, Guinea-pig 5 (*630 grammes—control*).—Result: Tetanic symptoms first observed after 38 hours. Death followed tetanic convulsions after 66 hours.

Guinea-pig 6 (*700 grammes*).—Oxygen injected after inoculation. (*Note.*—Some of the oxygen injected bubbled outward through a drop of blood at the point of inoculation, indicating that the wound was being well bathed with the oxygen, which would thus be brought into direct contact with the bacteria and prevent their development.) Result: Tetanus symptoms first observed after 90 hours. Eight days after inoculation the pig was alive and active on three legs, and able to eat hay. The inoculated leg had been more or less extended and rigid for the last three days. It looked very promising for an ultimate recovery as though an active immunity was being established.

Pair 2, Guinea-pig 7 (*700 grammes—control*).—Inoculated. Result: Tetanic symptoms first observed after 36 hours. Death following tetanic convulsions after 50 hours.

Guinea-pig 8 (*840 grammes*).—Inoculated and given oxygen injection. Result: Tetanic symptoms first observed after 51 hours. Death following tetanic convulsions after 72 hours.

With this pair of guinea-pigs, as with the second pair in Series I., we noticed that while tetanus with fatal termination developed in both cases the time of onset of the disease and of death was much delayed by the oxygen injection.

We take it for granted that the reader is acquainted with the modern treatment of tetanus —e.g., use of antitetanic serum, hypodermic injections of dilute carbolic acid solution, anæsthesia for spasms, the darkened room, chloretone, &c.— but draw attention to the fact that the only treatment used in these experimental cases was the direct deep injection of oxygen into the wounds, and we assume that if the beneficial effects in these cited cases were due to the injection of the oxygen other anaerobic infections might be at least equally well benefited.

We do not say that these limited experiments prove conclusively that subcutaneously injected oxygen is a sure cure for tetanus, but we think the results obtained warrant their publication, and we feel justified, in view of the fatalities that are occurring in the war zone from tetanus, to call the attention of the medical men in attendance, and others, to the beneficial effects obtained from this treatment as in the above cases, with the hope that it may in some measure aid in the prevention of, or recovery from, the disease with the wounded.

A fuller account of the experiments will be published later, and further experiments are planned which it is intended shall be carried out in the immediate future.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

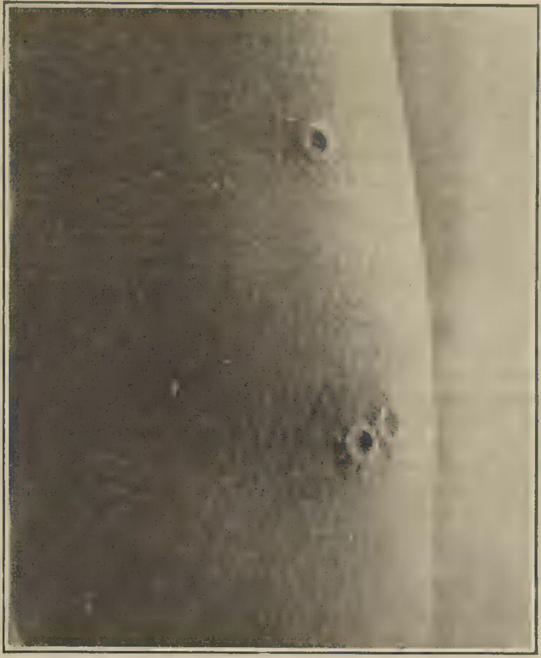
A CASE OF ANTHRAX.

By J. A. BENNETT, M.B., B.S. DURH.,
CAPTAIN, ROYAL ARMY MEDICAL CORPS.

ON account of anthrax being comparatively uncommon the following notes may be of interest to readers of THE LANCET.

History.—A driver in the R.F.A., age 30, was admitted to Connaught Hospital, Aldershot, with three pustules on his forearm. For about six months the patient had been working amongst horses and in stables, but had no recollection of having had any abrasions or the like. On March 3rd he noticed three spots on his forearm, two close together 2 inches below the end of the elbow, and the other 2 inches nearer the wrist. He felt "out of sorts," ascribing his condition to a cold, and it was on account of the latter that he reported himself sick on the 4th. The pustules had then the following appearance, small ulcers, ¼ inch in diameter (those shown in the illustration are slightly smaller than natural size), with elevated edges, the latter being due to small vesicles having coalesced and formed a complete ring surrounding a dry, depressed centre of a blackish-purple colour. Immediately outside this ring was an angry red area of about a quarter of an inch, on which were minute discrete vesicles irregularly concentrically placed. The whole skin of the forearm was indurated and inflamed. There was no febrile or constitutional disturbance of note.

Treatment.—After examination of many cover-glass preparations stained with watery methylene blue made from the pustules no B. anthracis were found, but as the appearance of the pustules was so suggestive of anthrax the patient was given an anæsthetic and the pustules were excised, including the vesiculated area. The raw surface left was cauterised with pure carbolic. Readily assimilated nutritious fluid nourishment and stimulants were given.



Pustules on the forearm in a case of anthrax.

Bacteriological examination.—Agar tubes and plates were inoculated with serous fluid aspirated from the pustules after excision, 24 hours' incubation showing a rich growth of staphylococcus albus, which obscured any other growths which may have been present; incubation was continued for three days. A flask of normal saline inoculated with some of the dense growth by means of a glass rod, and the saline emulsion was then heated at 85° C. for 30 minutes and stroke cultures made on agar plates from the latter. 24 hours' incubation of the agar plates showed numerous colonies of B. anthracis. To the naked eye and low-power examination the colonies were quite characteristic. Examination under 1/12th inch oil immersion revealed the characteristic B. anthracis.

Convalescence has been progressive and the man has been discharged from hospital feeling very fit.

I am indebted to Temporary Lieutenant R. Francis Jones for carrying out the bacteriological work, and to Temporary Lieutenant D. J. Legge for the surgical work.

South Farnborough.

VESICAL CALCULI IN VERY YOUNG BOYS.

By W. E. NICKOLLS DUNN, M.B. LOND.,
SUPERINTENDENT MEDICAL OFFICER, LUXOR HOSPITAL FOR NATIVES, UPPER EGYPT.

THE following brief details of two cases of vesical calculi in boys may be worth placing under the notice of readers of THE LANCET.

In the first case the patient, a plump little Arab boy aged 2½ years, was brought to hospital in November, 1911, because he was passing blood from the penis and his urine was constantly dribbling away. The sound entered the bladder with difficulty and there was no click heard. As the father of the boy was much upset at the child's screams the sound was at once withdrawn, and it was decided to take the patient in and examine him under chloroform. On the following day the child was duly anæsthetised. When the abdominal muscles were relaxed under the chloroform it was found that the fundus of the bladder lay just above the level of the umbilicus. The sounding of the bladder again failed to elicit any click, but the sound seemed to scrape against something as it entered the bladder. On passing a catheter only a few drops of urine escaped. An attempt was then made to distend the bladder with fluid, but without avail. The bladder was at once opened by the suprapubic route. No urine escaped, and it was found that the whole of the interior of the viscus was occupied by a smooth stone. My colleague, Dr. G. V. Worthington, grasped the bladder between his two hands and an assistant supported the stone with his finger in the rectum while it was being fractured with a mallet and chisel. Fortunately the stone was not a very hard one, but the pieces thus fractured were far too large to be withdrawn through the small wound in the bladder wall. A small lithotrite was then carefully passed around the side of the stone, between it and the bladder wall, and the female blade was slowly withdrawn until a portion of the fractured stone was grasped. An assistant then hammered the top of the supported lithotrite until the blades could be locked and screwed home. This manœuvre was continually repeated, and alternately the nozzle of an irrigator was introduced and the débris flushed out. Eventually the lower part of the bladder was by these means completely emptied. It was then thought that the rest of the stone could be pulled or pushed down from the upper portion of the bladder and more speedily dealt with. However, the stone fitted so tightly into the bladder that it was impossible to move it *en masse*, and it had to be carefully nipped off bit by bit by various kinds of forceps right up to the fundus. It took altogether two hours and a half to break up and evacuate the stone, the child being on the operating table two hours and three-quarters. For 48 hours after the operation the little patient was feverish and restless, but his subsequent recovery was uneventful. The surface of this stone was smooth and its colour brown.

The second case was that of a boy three years old who was admitted to hospital with a large stone on the same morning as the previous patient. The stone was a mulberry calculus, extremely hard and very irregular externally. The contrast between the two cases was remarkable. The boy in this case was in agony, owing to the roughness of the calculus; he neither ate nor slept, and was in consequence a living skeleton. The boy in the other case (whose bladder resembled a hard-boiled egg, the contents of the egg being the stone and the shell the bladder wall) experienced discomfort only and was quite robust in appearance. As in the former, so in this case the stone was crushed by hammering on the lithotrite, as it was too large to engage without this manœuvre, and subsequent flushing out of the débris through the suprapubic wound. The boy rapidly put on flesh and convalesced uneventfully.

In each case the wound in the bladder was left open and the edges were stitched to the abdominal wall. No tube was used and the bladder was irrigated twice daily with warm boric lotion. Urine was passed by the urethra in both cases on about the tenth day.

Medical Societies.

ROYAL SOCIETY OF MEDICINE.

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.

Exhibition of Cases.—Suppurative Parotitis after Pneumonia.

A MEETING of this section was held on March 26th, Mr. T. H. KELLOCK, the President, being in the chair.

Dr. F. E. BATTEN and Dr. W. H. VON WYSS showed a case of the Atonic Form of Cerebral Diplegia (Foerster). The child, aged 3 years, was the first of two children, born as a breech presentation after version. He had been weak from birth, and never able to stand or walk. He could sit up and hold his head straight. There was some kyphosis in the sitting position. He had difficulty in getting up because he could not balance properly. Instead of lying down he dropped down powerless according to gravity. He could move his arms and legs freely, but all his movements showed a great deal of incoördination. There was marked hypotonia of the feet, which could be bent on to the tibiæ. There were hyperextension of the knee-joints and a certain amount of hyperflexion of the hip-joints; also some flexor and adductor spasm. When suspended by the axillæ his legs were extended and rigid. There was hypotonia of the different joints of the arms. When placed on his feet he could not stand unsupported, and when he attempted to walk his legs performed incoördinate movements. The tendon reflexes were active. The abdominal reflexes showed a marked overflow, so that the thigh muscles contracted. The plantar reflexes gave a flexor response. The muscles responded normally to galvanism and faradism. The cranial nerves showed nothing abnormal. The intelligence was not bad, but he could not talk properly, though he understood everything said to him. The Wassermann reaction both in blood and cerebro-spinal fluid was negative, and the cerebro-spinal fluid showed no chemical or cytological abnormalities.

Dr. E. G. L. GOFFE showed four cases of Ichthyosis in a family of six children. The dry, scaly condition of the skin began to show itself about two months after birth in each of the children affected. Dr. Goffe also showed two cases of ichthyosis in a family of five children.

Dr. J. L. BUNCH showed a case of Ichthyosis associated with Long-standing Superficial Ulceration of the Tongue. The patient, a boy aged 12, had had generalised ichthyosis since infancy. Chronic glossitis with superficial ulceration had been present since birth, but varied in severity at different times. His mental capacity was somewhat deficient.

Dr. EDMUND CAUTLEY showed a case of Pulmonary Regurgitation in a girl aged 15 years. History of scarlet fever at nine years, and heart affection then recognised. Last August, and again in December, some pain and swelling in the hands and ankles. On Dec. 29th she took to bed on account of shortness of breath, for which she was admitted to the Metropolitan Hospital on Jan. 8th, the pain having subsided a week previously. During her stay in hospital there was no evidence of rheumatic fever, no fever, and no change in the cardiac signs. She was rather high-coloured, big, strong, and well developed. Her periods occurred every two weeks. Enlargement of the right ventricle was shown by percussion, cardiogram, and skiagram. Over the pulmonary area a long, loud diastolic murmur, most marked over the third and fourth left interspaces near the sternum, and 2 in. to the left thereof, then rapidly lost in all directions; sometimes heard faintly along the right edge of the sternum. There was no thrill. The pulse was rather small and had no "aortic" character, and varied from 68 to 100 per minute. A blood count on Feb. 12th yielded 5,270,000 red and 8600 white cells. All the facts appeared to support the diagnosis of simple pulmonary regurgitation, except that the skiagram indicated displacement of the apex a little downwards and to the left, as in aortic regurgitation, but there was no evidence of the hypertrophy usually associated with aortic regurgitation and such a loud murmur. Dr. Cautley also showed a case of Ectromelus with Absence of Pectoral Muscles on the Right Side, and one of Deformity and Wasting of the Hands with Deformity of the Feet.

Dr. E. A. COCKAYNE showed a case of Sclerodermia with Congenital Contractures and other Defects in a male infant, aged 1 year. Premature first child of healthy parents. First seen five months ago, and found to have congenital hydrocephalus, deformity of both ears, marked congenital contractures of the fingers and toes, and less marked contractures of both wrists, left elbow, and both knees. Contraction of the skin round the nose and mouth was also noticed. A Wassermann reaction proved negative. On Feb. 9th, 1915, the mother noticed that the skin on the outer sides of both thighs was very hard. This condition appeared suddenly and painlessly. There were large, symmetrical areas of thickened skin on the outer aspect of each thigh. The skin was not changed in colour, did not pit on pressure, and was not tender. The surface was nodular. The skin over the abdomen was affected similarly, but to a much less degree. Since it was first noticed there had been no change.

Dr. **Reginald Miller** showed a case of Inherited Syphilis with Wassermann Reactions in a boy, aged 2, well nourished. First child, no miscarriages, full term, breast fed. Father: Infected December, 1911. Treated at Lock Hospital with mercury until April, 1912; then two doses of salvarsan. Wassermann reaction not tested, as he failed to report. Reported in August, 1912, no fresh symptoms; a weak positive reaction. Received eight doses of mercury intramuscularly. In April, 1914, reaction negative. Mother: No symptoms throughout. Conception about June 24th, 1912. Child: Born March 22nd, 1913. At 5 weeks, epiphysitis of left elbow. Was treated with grey powder for seven weeks, combined with inunction (two weeks). Treatment then stopped for two months, owing to doubt in diagnosis. At 5 months he developed scaly rash on buttocks. Was given antisyphilitic treatment, including inunction, from fifth to fifteenth months; none since. Wassermann reactions of child and mother (full test): At 5 weeks, child and mother negative; at 5 months, child and mother positive; at 9 months, child and mother positive; at 11 months, child negative, mother (after salvarsan and mercury) negative; at 15 months, child and mother negative; at 23 months, child and mother negative.

Dr. **E. G. Fearnsides** showed a case of Chronic Polyarticular Arthritis commencing in a child at the age of 2 years 4 months. Until April, 1914, the patient was a healthy child. He was breast fed for 12 months, walked at 11 months, and began to talk at 13 months. In April, 1914, he became ill in himself and subject to attacks of sweating; shortly after this the small joints of his fingers swelled, his knees enlarged, and he became unable to walk. The child first came under Dr. Fearnsides's observation on August 28th, 1914. He was pale, flabby, wasted, unable to use his hands or to walk. There were considerable muscular wasting of the extremities, and great peri-articular swelling of the joints of the fingers, wrists, knees, and ankles, and apparently some enlargement of the bones. Lymphatic glands not enlarged, spleen could not be felt. He sweated freely. Tonsils were not enlarged. No abnormal signs could be discovered in the heart, lungs, or abdomen. Neither albumin nor pus in the urine. Under massage and grey powder by the mouth he had continuously improved. By November, 1914, he was again able to walk. The anæmia and the peri-articular swelling of the knees, ankles, wrists, and fingers gradually diminished. The Wassermann reaction in the serum was negative. At the present time a blood examination showed: red blood cells 5,450,000 per cubic millimetre, white blood cells 11,500 per cubic millimetre, hæmoglobin 64 per cent., colour index 0·8, with the differential count—polymorphonuclear cells 48·6 per cent., small lymphocytes 38·4 per cent., large mononuclear cells 10·4 per cent., transitional cells 1·2 per cent., eosinophiles 1·2 per cent., and mast cells 0·2 per cent. Dr. Fearnsides also showed a case of Pseudo-hypertrophic Muscular Dystrophy associated with Amentia in a boy aged 8 years. As far as could be ascertained there was no family history of myopathy. His father and mother were normal. The patient was the youngest of four children and the other three were healthy. In walking and mentally he had always been backward.

Dr. **Eric Pritchard** showed a case of Pneumothorax. A girl, aged 12 years, was brought to hospital on March 4th, 1915, for sudden breathlessness, with some cyanosis and pain in the left side of chest. She had complained of the pain off and on for three weeks, but had been going to school until the day she came to hospital. No cough and no previous illness. On examination nothing abnormal was found in the chest; the heart was slightly dilated, but otherwise in the normal position. Patient refused admission and was taken home. She continued to complain of the pain and was faint at times. Two days later she was admitted; temperature 100° F., pulse 104, respiration 28. Physical examination as before. She continued to complain at times of pain in the lower and posterior part of the left axilla, but was otherwise comfortable. On the fourth day the pain became severe, dyspnœa marked, colour pallid, temperature 103°, respirations 64, and pulse 136. The heart's apex beat was in the fourth right space about 1 in. internal to the nipple line. The left side of the chest was immobile and distinctly full under the clavicle. The note was hyper-resonant, breath soumds scarcely audible, vocal resonance and vocal fremitus absent; coin sound obtained. In four days' time the respirations had come down to 28 and the pulse to 96, while the temperature varied from 100° to 101°; the patient was quite comfortable. The note at the left base behind became dull, otherwise there was very little change in the physical signs.

Mr. **Philip Turner** showed a case of Hydrocephalus and Spina Bifida with Deformity of the Legs in a boy aged 2½ years, with talipes equinovarus of right foot and bowing inwards of the right tibia. Knee-joint in normal position; patella could be felt. There was talipes equinovarus of left foot also, but left thigh was externally rotated, so that the popliteal space was directed forwards. The tibia was still further externally rotated, so that the foot, though actually in a position of marked equinovarus, was rotated outwards and the sole directed forwards. Flexion of the knee was impossible, but hyperextension could be produced to an angle of 90°. The legs were not completely paralysed, though they could be moved but little. The child seemed intelligent, and the vision was normal. There was incontinence of urine and fæces. The X rays showed that bones were all present except left patella. The long bones were narrow, unduly slender, with enlarged and indefinite epiphyses. There was some evidence of periostitis of the left femur.

Dr. **J. Porter Parkinson** read a short paper on Suppurative Parotitis following Pneumonia in a boy, aged 3 years, in whom examination of the pus showed pneumococci and a few staphylococci. Recovery was uneventful.

Bradford Medico-Chirurgical Society.—A meeting of this society was held on March 16th, Dr. A. Manknell being in the chair.—Dr. F. W. Eurich gave a microscopical demonstration.—Dr. W. Mitchell read notes of a case of Urinary Incontinence in a female cured by a para-urethral injection of paraffin. The patient had sustained a rupture of the urethra during a very prolonged and difficult labour. Though the urethra had been sutured and the canal remained perfectly intact afterwards, the incontinence continued and made her life miserable. Dr. Mitchell then tried injecting paraffin with remarkable results, the patient being able to retain the urine from that moment, and no recurrence had taken place.—The case was commented on by Dr. T. J. Wood, Dr. A. Bronner, and Dr. Manknell, and Dr. Mitchell replied.—Dr. W. Wrangham read notes on two cases of Vertigo induced by intestinal parasites. Both patients were women and the symptoms were of short duration. In neither case could any cause be at first assigned for the symptoms. In one case a tapeworm was after a time discovered, and in the other several round worms. The symptoms of vertigo completely and abruptly disappeared in both cases after the worms had been evacuated. Dr. Wrangham thought that this was conclusive evidence that the vertigo was due in some way to the worms.—Dr. H. J. Campbell drew attention to the numerous drugs now on the market that are being used indiscriminately as purgatives by the public, who seem to think that any drug credited with an action on the bowels is suitable for any and every case. He reviewed shortly the action of the different purgatives and explained the principles guiding selection of a certain drug for a particular case. Broadly speaking, he said, purgatives could be divided into vegetable and mineral, the former being more generally useful in early life and the latter after middle age. The vegetable drugs acted on a normal bowel and all along the bowel There was no absorption, their action being entirely on the epithelial cell. The mineral drugs, on the other hand, acted on a bowel more or less overloaded with food and exerted their influence on the vessels, the action being that of bleeding the patient into his own bowel. Great care and discrimination were required in the use of purgatives, and much harm was being done by the increasing abuse of them, which is growing to such an alarming extent amongst the public.—Dr. Wood and Dr. Wrangham discussed the paper, and Dr. Campbell replied.

Reviews and Notices of Books.

A Surgeon in Belgium.

By H. S. SOUTTAR, F.R.C.S. Eng. London: Edward Arnold. 1915. Pp. 217. Price 8*s*. 6*d*. net.

Mr. Souttar was until recently surgeon-in-chief to the British Field Hospital for Belgium. This hospital started work in Antwerp, and when driven out by the fall of that city moved to Furnes, a little town about 15 miles east of Dunkirk. From there, owing to the German advance, it moved to Poperinghe, about 15 miles south of Furnes in the direction of Ypres, and finally it was moved back to Furnes, where it still was in January of the current year. Anyone who wishes to read a tale of simple, unaffected heroism on the part of patients, doctors, nurses, bearers, and non-medical helpers, priests, nuns, and the incomparable lady whom Mr. Souttar calls "Madame," had better read this book at once. It is written in simple easy English, it is vivid and informing, and its pictures of the absolutely wanton and purposeless devastation wrought at Louvain, Termonde, Ypres, and other places should bring home to everyone for what a righteous cause we and our Allies are fighting and what a practically unpayable debt we owe to Belgium.

As to the purely professional work of the hospital it was very successful, and one great element of success was, as Mr. Souttar says in his chapter "Some Conclusions," that the hospital being "always close to the front, we received our cases at the earliest possible moment, and could deal with them practically first hand." Naturally nearly every wound was infected and generally soiled by "earth, manure, fragments of cloth covered with mud." In Mr. Souttar's experience, however, infection with tetanus and other virulent organisms was rare. Many of the wounds were excessively foul and these were treated by solutions of oxygen, and when protected with a thin piece of gauze, by being exposed to the open air, "the results were almost magical, for in two or three days the wounds lost their odour and began to look clean, while the patients lost all signs of the poisoning which had been so marked before. It may be partly to this that we owe the fact that we never had a case of tetanus."

An interesting phase of modern war surgery is the manner in which severe compound fractures were treated. Many of these were fractures of the femur, with a large infected wound, and several inches of the bone blown clean away. At first these cases were regarded with horror, splints proved unmanageable, the wounds had to be dressed, and any movement meant agony for the patient. So Mr. Souttar and his colleagues took to applying steel plates, and this somewhat bold stroke met with deserved reward, for, in Mr. Souttar's words, "Not only could the limb be handled now as if there were no fracture at all, to the infinite comfort of the patient, but the wounds themselves cleared up with great rapidity." So well did they do, that on the night of the bombardment of Antwerp one patient who had been operated upon for this condition only ten days previously walked downstairs with the aid of a dresser's arm.

The case narrated on p. 16 is a wonderful example of what good prompt surgery will do for a man with pluck and a sound constitution. The war has given rise to many instances of heroism and self-sacrifice, but perhaps to none finer than this of the Belgian officer who, with a hideous shell wound of the abdomen, dragged himself and a wounded companion for nearly a mile, crawling on his hands and knees. When too exhausted to drag his friend any more he left him under a hedge and managed to crawl for another half a mile, when he obtained help. At death's door he was brought to the hospital and treated, part of the operation consisting in making a short circuit. Three weeks later he was left in Ghent "to all intents perfectly well."

As journalists, too, our hearts go out to our colleague, "the editor of a well-known sporting journal in England." He was serving as a machine gunner on an armoured car and got shot through both tibiæ when standing at the back of the car. The driver not realising this started the car, whereupon the editor just had time to catch hold of one of the rear springs, and in this position, with two broken legs, he was dragged along the road for half a mile. When found he was unconscious and bruised all over. He was brought into hospital and did well.

Not only can Mr. Souttar write well on professional matters, but he has the power of making the devastation of war seem very real. For instance, of Termonde, the town which the Germans deliberately burned, he says: "No words can ever convey any idea of the utter destruction of the whole town or of the awful loneliness by which one was surrounded. One felt that one was in the presence of wickedness such as the world has rarely seen, that the powers of darkness were very near, and that behind those blackened walls there lurked evil forms. ...... One could almost hear the Devil laughing at the handiwork of his children."

We will end our notice of a first-rate book by giving an anecdote told by Mr. Souttar as a counterpoise to the heavy weight of wickedness accumulated by the Germans in their treatment of Belgium. The story is told at p. 197 and is shortly this. About half a mile out of Pervyse was a farm held by a Belgian outpost, and half a mile beyond this were two other farms held by Germans. One morning news was brought to Pervyse that some of the men at the outpost had been injured. Nothing could be done till nightfall as the road (the only one across the flooded land) was swept by German guns. Then two priests went out to the farm where they found the wounded beyond their powers of carriage. They went on to the farms in the enemy's occupation and asked for help. We give the rest of the story in Mr. Souttar's own words: "A few minutes later the astounded Belgians saw a little procession coming up the road. In front walked the two priests, and behind them came four wounded Belgians, lying on stretchers carried by German soldiers. They came right into the lines and they had a royal welcome. They all shook hands, and the little party of Germans walked back down the road amid the cheers of their opponents." Such deeds as this throw a light amid the dark places of war.

Surgical Materials and their Uses.

By ALEXANDER MACLENNAN, M.B., C.M. Glasg., Visiting Surgeon, Royal Hospital for Sick Children, Glasgow, &c. With 277 diagrams and illustrations. London: Edward Arnold. 1915. Pp. 252. Price 4*s*. 6*d*. net.

THIS little book is based on lectures given to students of the Western Infirmary, Glasgow. It includes an account of the various bandages, splints, dressings, sutures, and ligatures; also the methods of antisepsis and asepsis are described; and it closes with a description of most of the instruments employed in surgery. It contains, therefore, much that should be very useful to the student, the house surgeon, and especially to the practitioner who wishes to keep abreast of the ever-advancing tide of knowledge. The author, while describing the most recent methods, has not omitted some of the more classical ones, which are indeed still practised by some surgeons.

The book is very practical in its teaching, and evidently records the experience of a surgeon who is particularly attentive to details in his work—a matter of the greatest importance in surgery. With nearly all that he says we cordially agree, but we cannot quite concur in the statement that instruments which take to pieces should be avoided. The author tells us that such instruments are liable often to fall apart when least desired. This is to a certain extent true, but the tendency to fall apart at inopportune moments will rarely be exhibited if the locks are well made. Instruments fixed by a screw can be as efficiently sterilised by boiling as the others, but it is very difficult to remove blood or other material which makes its way into the joint.

Clinical Diagnosis: A Manual of Laboratory Methods.

By JAMES CAMPBELL TODD, Ph.B., M.D., Professor of Pathology, University of Colorado. Third edition, revised and enlarged. Illustrated. London and Philadelphia: W. B. Saunders Company. 1914. Pp. 585. Price 12*s.* net.

IN the review of the second edition[1] this book was welcomed as one likely to be useful to the clinical pathologist; that this has proved to be the case would seem to be indicated by its rapid appearance in a third edition. The book has been enlarged by some hundred pages and a considerable amount of new material has been added, while the original material has been carefully revised.

The practical character of the work is insisted upon by the author, and it is based on experience gained in teaching. This experience leads the writer to the conclusion that the majority of the errors of students arise from an inability to use their apparatus properly or from failure to recognise artefacts, rather than from ignorance of typical structures when properly displayed. In this most teachers would agree. The chapter on the use of the microscope has therefore been enlarged and a set of practical exercises has been added to assist the student to meet these difficulties. As a further help to the learner use has been made of variations in size and character of type, not only for the headings of sections, but also in the text to attract attention to important points in the subjects treated. The section on the urine, always an important one and one containing methods not usual in English laboratories, has been completed by the addition of a simplified Volhard test for chlorides, the urease method for detecting urea in urine, blood, and cerebro-spinal fluid, the Rimini-Burnam test for formaldehyde, and the phenol-sulphone-phthalein test for estimating the functional activity of the kidney. The section on the cerebro-spinal fluid, which in the second edition was rather scanty, has now been rewritten and is considerably enlarged and improved. Sero-diagnostic tests were not entirely neglected in previous editions, but these tests and the methods employed in carrying them out now form a new and important chapter which has been contributed by Dr. Ross C. Whitman. The complement-fixation tests for gonorrhœa, tubercle, cancer, and syphilis are given, and the cobra venom test for syphilis and Abderhalden's protective ferment test are included. With regard to the value of Abderhalden's test criticism is not only deprecated, but somewhat fiercely resented, but we may at least express doubts as to the wisdom of including such a test in its present stage of development and with its acknowledged difficulties in a text-book avowedly intended for the practitioner and student, rather than for trained laboratory workers.

Further tests have been added in the section on the gastric contents, and several new staining methods are given. The illustrations, which are chiefly reproductions of microphotographs, have been increased in number and in some cases replaced by better plates, while the original frontispiece has been changed for a plate showing varieties of blood cells. The printing, paper, and general appearance of the book are good, and the edition is a decided improvement on the previous one.

The Alimentary Tract. A Radiographic Study.

By ALFRED E. BARCLAY, M.A., M.D., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., Medical Officer to the X Ray and Electrical Departments, Manchester Royal Infirmary, &c. With 77 illustrations. London: Sherratt and Hughes. 1915. Pp. 195. Price 12*s.* 6*d.* net.

THE work of Dr. Barclay with the X rays in the investigation of disorders of the digestive system is so well and favourably known that it gives us no surprise to learn that the edition of his last work, "The Stomach and Œsophagus," was very quickly sold out. In the volume now before us the above work forms the basis, though it has been enlarged and altered in keeping with subsequent experience. This has gradually taught the author that in dealing with disorders of the digestive system it is no longer possible to consider one part as distinct from the others; that the various parts from the cardiac orifice to the pelvic colon are so intimately associated with each other through their nervous mechanism as practically to constitute one organ, and that referred signs and symptoms are the rule rather than the exception. Merely to demonstrate the presence of a gastric or duodenal ulcer is now no longer sufficient, and in Dr. Barclay's opinion these are most often secondary manifestations of disease elsewhere. Thus it has become necessary to extend this volume so as to take in the whole of the alimentary tract. The subject is as yet far from being worked out to finality, if, indeed, it can be said that we are not near the beginning; and this study of radiography will be no more than one of the milestones on the way, though a very important one.

All through this book we are impressed by the judgment with which observations are recorded and by the care taken in the conclusions to be drawn therefrom, the author being his own most severe critic while a generous one to the opinions of others. In dealing with the subject of the ileo-pyloric reflex he confesses himself unable to recognise Lane's kink radiographically, or to regard it as a cause of either ileal stasis or of this ileo-pyloric reflex—an interesting remark considering how much has been said on this matter by some radiologists.

It would serve no purpose to pick out any part of the book for special remark; it is one that must be studied as a whole, and if it shows some lack of system in its arrangement, this is easily accounted for by the transitional stage through which our knowledge is passing. We advise those interested in disorders of the digestive system—and that must surely include all medical practitioners—to study this book carefully.

JOURNALS.

Quarterly Journal of Experimental Physiology. Editors, E. A. SCHÄFER, W. D. HALLIBURTON, C. S. SHERRINGTON, E. H. STARLING, and A. D. WALLER. Vol. VIII., No. 4. London: Charles Griffin and Co., Limited. 1915. Pp. 303-397. Price 7*s.* 6*d.*—Researches on the Perfused Heart: Some Effects of Sodium Chloride, by W. Burridge. This is a very elaborate, well-illustrated, and illuminating contribution. It is well known that the perfusion of isotonic sodium chloride through the frog's heart leads to its arrest in diastole and loss of electrical excitability, and that isotonic sodium chloride is not an indifferent substance for muscle. The author, whose experiments were made on the frog's heart, shows that sodium chloride has an action in determining the sensitiveness of the reactions of the heart to a given concentration of calcium salts. An active displacement of calcium salts by sodium is a factor in the production of the diastolic failure which follows perfusion of isotonic sodium chloride through the frog's heart. The salts of sodium and calcium are antagonistic in regard to their mutual adsorption on the surface of certain of the heart colloids (surface effects); they are antagonistic in regard to the changes in the state of aggregation each induces in those same colloids (deep effects). The state induced by calcium is one unfavourable to its own activity in its function of tonus production; the state of aggregation induced by sodium favours these latter functions of calcium. The favouring action of sodium on these calcium functions outweighs its antagonism. Hence, if the amount of sodium chloride in a perfusing solution be increased, the effective action, in certain directions, of the calcium salts already present in that solution will also be increased, but at a distinctly later period, and *vice versâ.*—On the Relation between Calcium Salts and Alkalies of the Perfused Heart, by W. Burridge. That traces of alkali in the perfusing fluid cause arrrest of the frog's heart in the systolic phase is well known. The author finds that: 1. The increased tonus which follows the addition of traces of alkali to a solution perfusing the heart is dependent on the calcium salts in the perfusing solution. 2. It is suggested that this action of the alkali is mediated by a change in the state of aggregation of some of the heart colloids. 3. It is shown that the action of the alkali in inducing changes whereby the effective action of a given concentration of calcium in producing tonus is increased is antagonised by calcium salts. 4. It is suggested that calcium salts induce a state of aggregation in certain heart colloids which is unfavourable to their own activity in producing tonus. 5. It is shown that alkalies first prolong and then shorten the refractory period of the heart, and that a marked summation of contractions is made possible.—Experiments on the Effect of Low Temperatures on the Frog, by A. T. Cameron.—On the Movements of the Isolated Small Intestine and the Action of Various Drugs and Extracts upon Them, by Alexander Waugh Young. The gut of the cat was found most suitable. Pieces of a certain length were placed in a modified Ringer's fluid and the movements recorded. The method employed for these isolated pieces of intestine was a modification of that of Magnus. A large number of substances were studied. We only refer now to a few of them. Carbon dioxide has an inhibitory action on both the tone and movements of the intestine. If the action of CO_2 is prolonged the intestine is permanently injured and eventually killed. Hyoscyamine has a stimulating action; it can initiate the movements when they are absent. The pendulum movements are increased in size and made more regular, the tonus oscillations being partially or completely abolished. Stimulation is seen with 0·001 per cent. of concentration. Hyoscine has an action similar to that of hyoscyamine, but it is weaker, 0·02 per cent. being the weakest concentration having a distinct action. Both drugs inhibit the stimulation produced by pilocarpine. Cocaine has a stimulating action in strength from 0·001 per cent. to 0·01 per cent.; with higher concentration no stimulation is seen, but a marked regularising effect then appears; with 0·2 per cent. a paralysing of the intestine comes on. Inhibition of the action of pilocarpine does not occur. Choline produces a marked rise of tone in the isolated intestine; this occurs with a concentration of 1 in 50,000; with high concentration the pendulum movements are obliterated. Atropine inhibits the action. There is also mutual antagonism between the actions of choline and adrenalin. Neurine in its action resembles choline, but is more powerful; 1 in 100,000 produces an effect. Watery extract of the posterior lobe of the pituitary body has the effect of raising the tone and causing the development of large tonus oscillations. The action occurs only with high concentrations; thus two glands per 100 c.c. of Ringer's solution is the weakest extract to give definite results. Alcoholic extract has no action. Hemisine causes inhibition of the movements and lowering of the tone of the intestine; 1 in 10,000,000 produces a small but distinct effect. Extracts of spleen, thyroid and thymus, pancreas, liver, kidney, and brain give no definite results. Stomach contents inhibit the movements by their acidity alone. The contents of the small intestine have often a marked stimulating effect apart from, but to a considerable degree influenced by, their reaction. Extract of digesting gastric mucous membrane and of mucous membrane of small intestine, and also secretin, have, when neutralised, no definite action. Pancreatic secretion increases the tone. Indol inhibits the movements and lowers the tone. Bile has a similar action.—The Mode of Action of Pituitary Extract on the Mammary Gland, by Sutherland Simpson and Reuben L. Hill. The galactagogue action of the posterior lobe of the pituitary body (pituitrin) in lactating animals is now well recognised. If the action, which occurs 20 to 30 seconds after injection, is on the smooth muscle the result would be due to expulsion of the secretion already in the gland rather than to increased secretion. Two lactating bitches were used. The authors conclude that the flow of milk which follows the injection of pituitary extract is due to the action of the extract on the secretory mechanism of the gland and not on its muscular tissue, since barium chloride, which is a specific stimulant for muscle, produces no increase in milk flow. It is conceivable that the barium salt may inhibit the secretion of milk, although no such action is claimed for it; but this supposition is ruled out by the fact that the gland responds actively to pituitrin within three minutes after the injection of barium. E. A. Schäfer adds a note on the paper of Simpson and Hill. He favours the view that the complete emptying of a gland which obtains after an adequate injection can best be explained by supposing the existence of contractile tissue in the walls of the alveoli.—The Pyramidal Tract in the Striped Gopher (Spermophilus Tridecemlineatus—Mitchell), by Sutherland Simpson. We must refer the reader to the original paper, and the same must apply to two short papers on the Lipoid Content of Vascular Epithelium and of Peritoneal Epithelium by John Tait and William Campbell.

British Dental Journal.—In the March 15th issue of this journal there is an interesting paper by Mr. C. E. Wallis on Ancient and Modern Dentistry. He tells us that "extraction" was first recommended about the year 1300 B.C., while he refers also to the skill displayed by the Etruscans in the manufacture of gold dental bridges and similar appliances to replace lost teeth. He points out the influence of Fauchard, Heister, and Moaton on modern dentistry, and deals with the introduction of nitrous oxide. In a paper on Toxæmia of Oral Origin, Sir Rickman Godlee utters a word of warning against the reckless removal of all the teeth in cases of general disease suspected to be due to mouth infection. There is a paper by Mr. C. Every Brown on the Treatment of Sensitive Cavities.

DONATIONS AND BEQUESTS. — The late Mr. William Richmond has left his residence and grounds at Lancaster to the Royal Lancaster Infirmary and, subject to certain devises of real estate and legacies to relatives and friends, the net residue of his estate will be paid over to the trustees of the infirmary for founding, endowing, and maintaining a convalescent home to be called the Richmond Convalescent Home.—The late Mrs. Elizabeth Ellen Hopkinson, of Chesterfield, Derbyshire, has left by will £1000 to the Chesterfield and North Derbyshire Hospital and Infirmary.—The late Mrs. Elizabeth Winstanley, of Southport, has bequeathed £1000 to the Chorley Dispensary and Rawcliffe Hospital, Gillibrand-street.

THE LANCET.

LONDON: SATURDAY, APRIL 10, 1915.

The Medical Needs of the Army.

THE appeal of Sir ALFRED KEOGH, Director-General of the Army Medical Service, for medical men to meet the needs of the army[1] has not, we fear, been met with quite the alacrity which it deserved, though we have his acknowledgment that a very satisfactory number of applications have been received. That more men have not as yet applied has been due, perhaps, to the fact that the forms which are supplied from the War Office to qualified medical men wishing to obtain a medical commission in the Royal Army Medical Corps are not as informing as they might be, and certainly to the other fact that no special mention was made of the possibility of the employment of part-time service. Sir ALFRED KEOGH'S description of what he looked for was perfectly clear and simple, as far as it went. "We want," he said, "every qualified man who is physically fit and willing to serve." He mentioned the special need for general practitioners, though immediate employment could, he added, be given to all suitable men, "expert surgeons, ophthalmologists, radiographers, &c." The Director-General stated plainly that the emergency was a national one, and that while there was no desire to denude the country of civil practitioners, he hoped that every man who could arrange to have his work done at home would come [forward at once to keep up an adequate supply of medical service in the field.

We have had many communications arising directly out of Sir ALFRED KEOGH'S appeal, while we know that not only our contemporary, the *British Medical Journal*, but also many lay papers have similarly received letters from medical men desirous of helping, but uncertain how they could do so exactly. Those who were prepared to accept whole-time service were confused by the different conditions for commissions in the Royal Army Medical Corps and for Territorial commissions, and letters which have found their way into the press have not cleared up the difficulties. The three varieties of commissions available—viz., the two indicated and the R.A.M.C. Special Reserve—present differences in pay and employment which are not so easy for the layman to deal with as the military mind might conceive, but at the same time we are bound to say that we think many of the medical men who are anxious to serve would find these difficulties could be got over, if they were willing not to hedge their offers round with too close reservations. We know that many such medical men, however, must be prepared to make large sacrifices. What we would urge them to believe is that the War Office is only too anxious to obtain their assistance, and fully recognises that, in many cases, their aid must be forthcoming at both certain loss and possible risk to themselves. There has, moreover, been a widespread feeling, and one which has been openly alluded to in our columns, that in certain localities our forces were not only well supplied but over-supplied with medical officers, so that what was required was perhaps rather a re-sorting of material than the recruiting of new men. In Scotland, largely through the energy and initiative of Dr. NORMAN WALKER, the convener of the Scottish Medical Service Emergency Committee,[2] there has been a brave attempt at organising the medical profession in such a way that those who joined the army should have their interests cared for by their brethren remaining behind, a certain proportion of the pecuniary risk run by those who were with the colours thus being obviated; but hitherto in England no attempt of the kind has been made. These are the things which have possibly kept many very suitable medical men from responding immediately to Sir ALFRED KEOGH'S appeal, while the inability, apparently, to make use of the part-time services of the general practitioner has also helped to leave the army short-handed. The following is an extract of a letter which we received this week, and which we reproduce because it exactly expresses the feelings of many general practitioners:—

> "I am wondering," writes a valued correspondent, "what is likely to be in process of arrangement *apropos* of the dearth of doctors and the possibilities of having to make use of part-time service men. I cannot leave my practice, but I should be glad to be useful if possible by giving certain hours on certain days or indeed every day. In order to meet the emergencies of general practice I could arrange with a neighbouring doctor, a friend, that one of us would be always available at arranged times within some reasonable distance of the road in which we live, to carry out medical duties under orders. I have no doubt there are many situated as I am, with no experience of the military side of the R.A.M.C., who are only awaiting the chance of making themselves useful in this emergency."

There were, as our correspondent guesses, many practitioners whose thoughts were running in exactly his own grooves. Doubt as to the conditions of military service, doubt as to the real need for their help, and doubt as to the possibility of giving to the army a part of their professional time—these things accounted for many abstentions.

Such was the position when just before Easter it was decided by the British Medical Association to invite Sir ALFRED KEOGH to a conference with a special committee of the Association. The Director-General accepted the invitation, and, accompanied by Colonel A. P. BLENKINSOP, the Assistant Director-General in charge of questions of personnel, met the committee of the British Medical

[1] THE LANCET, March 13th, 1915, p. 572.

[2] THE LANCET, August 22nd, 1914, p. 530.

Association on Thursday, April 1st, when he made a statement which should, in our opinion, go far to clear up the existing difficulties. Dealing in the first place with the widespread conviction that there was an abundant surplus of medical officers in some places at home, he pointed out that such surplus was only apparent, and that there was a place for every one of the men now holding commissions to serve with units which would be sent abroad probably in a very short time. He assured the meeting that when everything that distribution could effect had been done, there would remain a serious shortage of whole-time medical officers to serve with the troops wherever they might be sent. He then made the statement, which appears on p. 775 of this issue of THE LANCET, wherein, while warmly acknowledging the assistance already received from the civil medical practitioners of the country, he accepted the fact that the help now required must be given upon the part-time principle. Mr. T. JENNER VERRALL, the Chairman of Representative Meetings of the British Medical Association, promised that the Association would do all in its power to arrange some scheme of mutual aid, while medical men have before them the excellent example of the Scottish Medical Service Emergency Committee as a guide. We feel certain that medical men who respond to Sir ALFRED KEOGH'S repeated invitation to apply to the War Office, if they desire to help the country at this juncture, will find that any doubts they may have as to the conditions of service will be removed. The conditions may call upon their patriotism, but they need not also be a puzzle to their intelligence.

◆

Convalescence and Sick Leave in the Army.

EARLY in the war a wave of pity led many to prepare to do their best for wounded soldiers. Throughout the kingdom in private dwellings preparations were made for the reception of small numbers of men, in pathetic ignorance of the difficulties that might be encountered if they ever arrived. Our benevolent citizens could scarcely be expected to realise that the cordiality of their move might be embarrassing or even unwelcome to the authorities. The offer of kindly treatment, of good food and surroundings, and of personal devotion seemed to mean so much when freely tendered that officialdom was blamed unjustly when the days passed without any tangible recognition. Numbers of wounded arrived in this country, were treated in hospital, and then, so far as the members of the public were aware, they were sent out on sick furlough and returned to their homes, where the conditions must frequently be far from the ideal of convalescence. In the near future the pressure on the accommodation available at the hospitals will induce a natural tendency to discharge the wounded or sick soldier on sick leave at the earliest moment possible, but it will be mainly to convalescent institutions that he will go. Private hospitality is too devoid of regulation to be useful, while the unsatisfactory nature of the food in the homes of the soldiers on sick furlough makes reception by their families inadvisable.

There is perhaps no subject upon which medical advice is more frequently sought than the question of the best method of bridging over the interval which must occur between the bed of sickness and the activity of daily life. For ordinary patients this interval is half way between the control of the physician and the resumption of whatever free will is permitted by the ordinary occupation. During the interval the control of authority is relaxed to some extent, while by degrees the convalescent man feels that, with returning strength, he is fit to run alone. Though the control is relaxed advice is desired. The medical man is asked where the time of convalescence should be spent, how the days should be occupied, what treatment, if any, should be continued, what rules of life should be followed. The answers to all these questions are dependent on the nature of the previous illness, and to a great extent they must vary with the circumstances of the patient. In general terms it may be thought to be sufficient to advise a convalescent home for those who have been inmates of hospitals. Further inquiry, however, soon shows the limits of this panacea. Many convalescent homes rigidly restrict the class of patients to be admitted; apart from questions of surgical dressings or continued surgical treatment, it is often found that the patients in convalescent homes are required to be able to perform various personal services. For those more happily circumstanced, medical men are asked to consider whether the time of convalescence is to be spent at some specially selected place, or whether it may not be more conducive to quick recovery for the patient to go to friends living in the country. Undoubtedly sympathy and kindly intercourse are factors which must often be reckoned with. They are of inestimable service when they tend to distract from the memories of the period of danger; they may be positively harmful if, through lack of tact, they encourage gloomy reminiscences.

The soldier on sick furlough occupies a position which is scarcely comparable to that of a civilian. It may be assumed that his wounds or illnesses have not been sufficiently disabling to remove all hope of future service, and it therefore is desirable, in the interest of the nation, that he should be restored to efficiency at the earliest date. On the other hand, if he is one who has returned from foreign service he has earned a furlough which he might legitimately desire to spend with his wife and family. Provided that this can be accomplished without impairing his efficiency, the dictates of humanity would offer no obstacle. Speedy restoration must, however, be the first consideration, and for this it must, we think, be freely admitted that the life of routine in a suitable convalescent home offers the best prospects. The home would require to be under military discipline, since the cheeriness of the convalescent soldier might be misunderstood and even be troublesome in a home where civilians were received. With judicious management and understanding the convalescent soldier is a most delightful being, but he requires just a little control occasionally, and to be effective this control must be exerted by someone whose authority he respects. The difficulty of arranging for continuous supervision is perhaps the reason why so many of the offers of convalescent treatment have not been accepted by the authorities at the War Office. It might perhaps be possible to arrange for a non-commissioned officer to be responsible for due observance of regulations in small convalescent homes, but it is probable that more satisfactory results would be attained by the formation of larger homes, which should be under the management of permanent officials with military rank. On leaving such homes the men should be physically fit for service and should only be entitled to such further furlough as is necessitated by their work in the front. While under convalescent treatment in a home, or while on furlough subsequently, there can be no doubt of the importance of a sufficiently liberal diet or of strict limitation of alcohol.

◆

Compulsory Notification of Measles, Rubella, and Whooping-cough.

A CIRCULAR which has been issued by the Local Government Board to local authorities states that the central department is willing, on the application of any sanitary authority, to make compulsorily notifiable the first case of measles, German measles, or whooping-cough which occurs in a household in the district concerned. It becomes important, therefore, to consider the advantages which the adoption of local notification of these diseases is likely to secure.

It is not at all probable that notification can lead to much diminution in their prevalence or in their regular recurrence at epidemic periods. All three diseases are highly infectious during the days before the characteristic symptoms lead to medical aid being called, and the ability to infect will in most cases have been freely exercised before any intimation can have reached the local authority. The notification of measles has, in fact, been tried in a large number of areas in the past, and in many cases has been abandoned on the ground that no appreciable impression was made on the figures of measles prevalence, and that no obvious benefit resulted from the considerable sum spent on notification fees. Judged by the standard of prevalence notification of whooping-cough and of rubella would probably be equally disappointing. There is, however, another side to the case. Taking the 1912 return of the Registrar-General for England and Wales as an example, measles caused 12,756 deaths in the year and whooping-cough 8407 deaths, and these figures were not exceptionally large. Local health authorities and the public generally have become alive to the seriousness of the measles and whooping-cough factors in the death-rate, and besides this are realising the large amount of invalidity, particularly that due to ear mischief, which results from the complications of measles and secondary septic infections. The frequency with which tuberculosis supervenes on attacks of both diseases is also well known. In respect of fatality and of complications there is a very striking contrast between children of more well-to-do parents—who can be isolated in airy rooms, receive adequate medical and nursing aid, and be well looked after and fed during convalescence—and the children of working-class households who are usually under much less favourable conditions. Public health authorities can set themselves to reduce the handicap of the latter class. Owing to the numbers concerned routine treatment of measles in isolation hospitals is hardly practicable, though these hospitals should be available for special cases. But much can be done by systematic and frequent domiciliary visits of trained nurses, and by health visitors under medical supervision, to see that in working-class homes the best available conditions are secured during illness and convalescence, and that medical advice and other practical assistance are obtained where needed. Authorities prepared to make arrangements on these lines will find the adoption of compulsory notification of great assistance to the work.

The system in the case of measles, rubella, and whooping-cough is, however, exceptional in that no approach to completeness can be expected unless parents themselves accept the obligation to notify. As a strict matter of law, parents are already liable under the Notification Acts, in addition to the medical practitioner, for notification of the diseases to which these Acts apply, but in practice this obligation has seldom been enforced or recognised to be binding. It will be important to ascertain by experience how far notification by parents can be successfully pressed in regard to the diseases here in question, as it may well be the case that the children needing the greatest amount of attention will be found in households where notification requirements have been neglected.

BY the will of the late Mr. George Stowell, of Great Torrington, the testator left, subject to the life interest of his wife, £1000 to the trustees of Epsom College upon trust, to pay the income for one year to a boy, who shall have been educated at the school for five years, to enable him to further his training.

Annotations.

"Ne quid nimis."

THE ALCOHOL QUESTION IN RELATION TO THE ALCOHOLIC STRENGTH OF BEVERAGES.

THERE appears to be a considerable amount of misapprehension in the public mind as to the alcohol value respectively of spirits, wines, and other beverages. Strictly speaking, a total prohibition order would exclude all fermented beverages, including ginger beer (made with yeast, sugar, and ginger), which may reach an absolute alcohol strength of 2 or 3 per cent. by volume. No beverage, of course, which has been fermented can be free from alcohol. On the other hand, there are a number of effervescing beverages—e.g., ginger ale, lemonade, "tonic" water—which are not fermented at all, they are simply solutions or infusions of the various ingredients aerated with carbonic acid gas under a small pressure. Broadly speaking, alcoholic beverages can be divided into the following groups in the order of their alcoholic strength: Spirits—whisky, gin, brandy, and rum containing about 50 per cent. of alcohol by volume; fortified wines—port, sherry, and madeira containing about 23 per cent. of alcohol by volume; unfortified or the so-called natural wines—some pale sherry, claret, moselle, hock, burgundy, and sauterne containing approximately 12 to 13 per cent. of alcohol by volume. In this group may be included champagne and saumur and sparkling hock, although these may be slightly liqueured. We find, however, that they seldom contain more than 14 per cent. of alcohol by volume. The last group comprises cider, perry, and beer. The alcoholic strength of cider is about that of light beers—viz., approximately 6 per cent. by volume of alcohol. There are, however, two classes of beer, the heavy or high gravity beers and the low gravity or light beers, the former containing about 2 per cent. by volume more of alcohol. The foregoing figures have been obtained in our own laboratory and have been often tested. It is important to remember that beers are sharply distinguished from all other alcoholic liquors inasmuch as they contain a decided amount of nourishing material in the shape of carbohydrates and proteins derived from the malt. The absorption of alcohol is retarded in the presence of food substances and also by free dilution with water. Recent events appear to show that owing to the extra taxation of beer there has been a decided decrease in its consumption and a corresponding increase in the consumption of spirits and especially of whisky. There are reasons for believing that the very cheapest and immature whiskies have thus replaced the much more wholesome malt liquor. If that is the case the extra taxation of beer with the object of gaining increased revenue was unfortunate. The brewing industry, especially if it be confined to brewing light beers, is much less likely to do harm than the distilling industry, which is bound by statute to keep up its product to a very high alcoholic strength. Of wines, a pure natural claret is undoubtedly the most wholesome, and the best non-alcoholic beverage is "dry" ginger ale.

ANGELO CELLI.

THE Roman Società per gli Studi della Malaria (writes an Italian correspondent) has undertaken to erect a monument to the memory of the late professor of State hygiene, Dr. Angelo Celli, to attest its appreciation of his work as the inspiring and guiding spirit of the society in question. The site of the memorial will be a commanding spot in the Agro Romano, to the rehabilitation of which, in a sanitary as well as an agricultural sense, Dr. Celli contributed so assiduously and so well.

GENITAL INFECTION IN LEPROSY.

THERE is a widespread belief among some native races, the Chinese and Japanese, for instance, that impure sexual contact plays a part in the spread of leprosy. Our contemporary, the *American Journal of Tropical Diseases and Preventive Medicine*, has, in an editorial article in a recent number, called attention to this subject. At the present time our knowledge of the ways by which the disease is propagated is defective, and as a consequence it is possible that our efforts to prevent it may not be altogether carried out in the proper directions. The presence in lepers of nasal discharges containing the bacillus lepræ has been regarded as probably concerned in the diffusion of the malady. A few writers on leprosy have at times expressed the opinion that unclean sexual intercourse may be responsible in some cases for the development of the infection; but it cannot be said that hitherto any very convincing facts have been reported to support this view. The article to which we have referred above brings forward some evidence bearing upon the point, and quotes the statements of Dr. E. Jeanselme in the *Bulletin de la Société de Médecine Exotique*. Sometimes, it is alleged, lepromata form in or near the genital organs, and in certain instances pus containing "myriads" of B. lepræ can be squeezed from the urinary meatus. Dr. Jeanselme describes the case of a South American leper living in France upon whose glans penis lepromata were present encroaching upon the meatus, and who had suffered for some time from difficulty in passing his urine. From the urethral discharge of this patient Hansen's bacilli were obtained. In this instance the bacilliferous urethritis was of the gravest importance, since the man was still at the height of his sexual activity. It is suggested that leprous urethritis is not so rare as is commonly supposed, and careful examination would probably often reveal its existence in unsuspected cases. In the later stages of leprosy the sexual powers decline, but they are active in the earlier period of the disease. Systematic examination is proposed in all cases, and where urethral discharge is present it is recommended that the patient should be strictly isolated to prevent any further mischief to others.

STREET ACCIDENTS CAUSED BY VEHICLES.

A RECENT return showing the number of accidents resulting in death or personal injury known by the police to have been caused by vehicles in streets, roads, or public places during 1914 comprises a period during which in London and in many sea-coast towns street lighting at night has been diminished or forbidden. To some extent this incident of war may account for a rather marked increase in the number of accidents which took place during last year as compared with 1913, and it will be of some interest to observe, when the statistics of 1915 are published, whether an increase in the number of darkened areas, and in the strictness of the regulations as to this measure of precaution, as well as with regard to lights on vehicles, can be said to have had any marked effect in augmenting the danger to pedestrians and to others inseparable from motor-driven and other vehicles. Horse-drawn vehicles in any case grow fewer and so do the accidents which they cause. The deaths officially ascribed to them in England and Wales during 1914 numbered 520, as against 554 in 1913; in Scotland 64, as against 86; and in Ireland 49, as against 84. Probably the demand for horses for war purposes, as well as the increase of motor traffic, must be taken into account in connexion with this diminution, but we must also remember, when considering the number of accidents in which motor vehicles have played a part, that in the last months of 1914 an enormous number of our private and other vehicles were already at work on the continent. In England and Wales the number of accidents due to motor vehicles and reported to the police were, in 1914: fatal 1334, non-fatal 29,891; in 1913: fatal 1189, non-fatal 26,135. The corresponding figures for Scotland are: 1914: fatal 142, non-fatal 2308; 1913: fatal 133, non-fatal 2064; and for Ireland: 1914: fatal 53, non-fatal 873; 1913: fatal 53; non-fatal 728. The total increase of accidents due to vehicles of all kinds amounts to 63 so far as fatal accidents are concerned, and to 3994 with regard to non-fatal accidents. It may be suggested that of these the numbers which relate to deaths are likely to be more uniformly accurate than those tabulated with regard to non-fatal accident. Even a severe accident not causing death may never come within the cognisance of the police, and the proportion of accidents thus escaping record must vary according to local circumstances. Be this as it may, the latest police statistics of accidents show an increase which may or may not continue in future years, and, as has been suggested, the war has afforded at least one cause for an upward movement, while another would be an increase, also due to war, in the number of inexperienced drivers. Both these circumstances will have existed in even greater degree during the past three months than during the closing quarter of 1914; but, on the other hand, we must not forget the fact, referred to above, that a very large number of vehicles which otherwise would be circulating upon the highways of the United Kingdom are now abroad. Upon the whole, therefore, it may be wiser to wait until peace has restored normal conditions and not to draw inferences rashly from the figures above quoted, but merely to note that there is an increase in the number of accidents. This must be to some extent due to the popularity and usefulness of the motor-propelled vehicle having increased the number of vehicles on our roads, and has not been necessarily caused by any general negligence on the part of drivers or by any dangerous qualities inherent in this form of locomotion.

THE OPEN TREATMENT OF WOUNDS WITH IODINE.

Dr. Marco Pezzolo has been following up the suggestions made by Professor Alcock, of Edinburgh, as to the advantages obtained by dispensing with the use of antiseptic dressings for wounds. He gives his experiences in a recent issue of *Il Policlinico* and they seem to endorse Professor Alcock's views in that his results were entirely favourable. He makes use of a 4 per cent. solution of iodine in commercial methylic alcohol which should contain from 1·5 to 2 per cent. of acetone, and should be freshly prepared, since stale preparations give rise to irritating fumes. In this detail he differs somewhat from Professor Alcock, who uses a much weaker solution, 2 parts of tincture of iodine B.P. to 98 parts of methylic alcohol, and who attributes the absence of irritating fumes to the use of methylic instead of ethylic alcohol. Dr. Pezzolo made a bioscopic examination of skin treated by painting it three times with this solution at half-hour intervals, and demonstrated the penetration of iodine by means of the reaction between it and a weak solution of nitrite of potash acidulated with acetic acid. He then adopted this method in treating his cases of operation. At first he painted the wound daily after the operation up to the seventh day, but afterwards he limited this treatment to the fourth or even the third day, according to the extent of operative interference, the wound being often hermetically closed by that time. He also at first covered the wound with a dry sterile pad, but latterly discontinued this, the patients merely wearing the sterilised hospital garments. He was at particular pains to ensure complete hæmostasis and perfect adaptation in suturing, and recommends this method in all cases where there is no need to use drainage-tubes or bandages for supports.

TICK PARALYSIS.

SINCE the first proof was afforded that disease may be conveyed by the bite of insects and other parasites, quite a considerable number of affections have been traced to this source of inoculation, and others are constantly added to the list. One of the most recent is the form of paralysis associated with the bite of ticks, which has been observed in British Columbia and in Wyoming and Montana, as well as possibly in Australia. The subjects of the disease are usually children, and the symptoms are flaccid paralysis of the legs with some rise of temperature and considerable quickening of the pulse. If the tick is found and removed promptly these symptoms quickly subside and the child gets well again within 12 or 24 hours without any residual ill-effects; but if this treatment is omitted the paralysis may spread to the arms, stupor may supervene, and the child may die with general paralysis in a condition of coma. More rarely a somewhat similar but milder condition may be produced in adults, the symptoms being pain, vertigo, and incoördination, accompanied by an erythematous rash in one instance. It would seem that more than one kind of tick may be responsible for the conveyance of the disease: thus both the genus Ixodes and the genus Dermacentor have been incriminated. A form of paralysis in the sheep of British Columbia is associated with the presence of tick, and Hadwen was successful in producing the condition experimentally by causing a tick to feed on a lamb, while later, in conjunction with Nuttall, he induced the same symptoms in a dog. Todd,[1] who has recently given an account of the affection, made a series of experiments on monkeys, lambs, puppies, and a guinea-pig, but failed to obtain any definite positive results, nor did an extract of ticks produce paralysis when injected into rats. The disease clearly needs further elucidation, and the existing difficulties will doubtless be cleared up now that attention has been fairly called to the existence of the affection. It appears to be an intoxication rather than an infection, if one can judge from the rapid disappearance of symptoms when the tick is entirely removed, whereas if only the head of the parasite is left in the skin the paralysis may persist and even progress. If the possibility of the presence of a tick be not borne in mind the condition might be mistaken for simple convulsions or for infantile paralysis.

THE EFFECTIVENESS OF TOOTH-WASHES.

THERE are few persons now who have not the conviction that the scientific cleansing of the teeth and gums is very valuable, and the business in antiseptic dentifrices is obviously increasing, judging from the numerous public advertisements which appear in the daily press setting forth the merits of a great number of these preparations. Generally speaking, they are so composed as to render them well adapted for the purpose, and we have submitted a number of them to analytical examination. The choice of antiseptic is commonly confined to carbolic acid, thymol, peppermint, boric acid, benzoic acid, eucalyptus and other essential oils, distributed in vehicles containing as an agent of attrition non-gritty chalk and as an alkaline medium soap. Experiments are usually quoted as to the actual germicidal value of these preparations *in vitro*, but of course it would be more satisfactory to have evidence of their real effect in the mouth where very different conditions must as a matter of fact exist. The use of a tooth-wash does not approach the conditions of a laboratory test, though there can be little doubt that a good deal of germicidal work in the mouth is done by the vigorous application of the toothbrush, and it may be pointed out that the tongue may well be included in the process. To be effective, however, the action of all antiseptics takes time, according to the vitality of the organisms they encounter, and usually the tooth-brushing process does not occupy many seconds. This question of time-exposure is important, but it is very generally overlooked, and consequently the antiseptic treatment of the teeth falls short of that effectiveness which is shown to be the case in laboratory experiments. The tooth-washing process should be more prolonged and the antiseptic wash allowed to remain in contact with the teeth and gums for some minutes instead of seconds before finally washing the mouth clear of antiseptic with plain water.

CONGENITAL DIAPHRAGM OF THE LARYNX.

ACCORDING to Sir StClair Thomson there are but 20 cases of congenital diaphragm of the larynx on record. In the *Saint Paul Medical Journal* for February Dr. G. B. New has reported the following case from the Mayo Clinic, Rochester, Minn. A well-developed and healthy man, aged 27 years, had been hoarse since birth with no apparent change of voice. On exertion, such as running up stairs, he had slight difficulty in breathing. Laryngeal examination showed a thin membrane extending between the margins of the true vocal cords for two-thirds of their extent anteriorly with a concave margin towards the lumen of the glottis. The membrane was pale grey, gradually fading into the margins of the cords, which were rounded and slightly reddened. It appeared thinnest in the median line and at its free margin, and did not show any scarring. The larynx was otherwise normal. During phonation the membrane almost disappeared, but enough remained to prevent approximation of the cords. The Wassermann reaction was negative. Congenital diaphragm of the larynx was diagnosed because of the history of hoarseness since birth, the absence of any illness which would account for such a condition, the appearance of the diaphragm, and the otherwise normal larynx. With a laryngeal knife the membrane was split down the centre from the free margin to the anterior commissure. As the knife approached the anterior commissure there was increased resistance on account of the greater thickness of the membrane. Although measures were taken to prevent it, adhesion of the cords at their anterior part occurred. After the reaction from the operation the voice was slightly improved and breathing easier. As to the origin of such membranes, Ganghofner has shown that the larynx is developed from two symmetrically placed ridges which bound a small fissure. At a certain stage of development these ridges lie close to each other and are attached by epithelial adhesions. The membrane is due to the persistence of these adhesions. Heredity seems to play a part, though in the present case there was no family history of such a condition. A case has been recorded in which the father and sister of a patient had similar formations, and a case in which the mother of a patient had congenital adhesions of the cords at the anterior commissure. Other congenital deformities—shortening of the frænum linguæ and coloboma of the upper lid—have been found associated with congenital laryngeal diaphragm. Microscopic sections have shown the presence of mucous glands and muscle fibres in the diaphragm. Flat epithelial cells were present on the upper surface and cylindrical epithelial cells on the under surface similar to those of the cords. A congenital diaphragm of the larynx is usually in the anterior part, but two cases have been reported in which it was in the posterior part. The diaphragm varies in size from a simple rounding of the angle of the anterior commissure to that present in the case described above. Rounding of the anterior commissure is not an infrequent finding in the examination of the larynx. Treatment, as a rule, has been unsatisfactory, because the raw surfaces of the anterior commissure unite again. Improvement of the voice usually is not marked, although the breathing is easier.

PITUITARY STANDARDISATION.

PHYSIOLOGICAL standardisation has for many years been a subject of controversy, and many efforts were made to induce the General Medical Council to adopt this method in the current British Pharmacopœia. It has been urged that this test affords the only certain method of obtaining uniformity of strength for various galenical preparations. Since the General Medical Council has not thought fit to introduce this innovation, it is not necessary to recount the various arguments adduced in its favour. It must be admitted that the latest contribution[1] is certainly not encouraging. It recounts experiments conducted with a view of comparing the physiological activity of some commercial pituitary preparations, and after a careful description of a large series of experiments the writer (George B. Roth) concludes that in a general way it may be said that the claims of the manufacturers are misleading, since the statement "physiologically standardised" means practically nothing. The tests employed were those known as the isolated-uterus method, and by these tests it was found that of two preparations claiming to be of the same strength one was 7·5 times stronger than the other. Altogether 11 different samples were collected, representing the product from six different manufacturers. They were all bought in the open market in sealed packages, and were kept in their original package in a cool dark place until used. The examination of these samples by the blood-pressure method and the intact-uterus and isolated-uterus methods showed them to possess a wide range of physiological activity, the ratio of variability between the strongest and weakest by the blood-pressure method being 15 to 1, by the intact-uterus method about 10 to 1, and by the isolated-uterus method about 7 to 1. The article concludes that the need for uniformity in the strength of commercial pituitary preparations has been made apparent. Incidentally it may be remarked that these experiments have also demonstrated the unreliability of some of the commercial claims connected with "physiological standardisation" and the urgent need of some central bureau of control before any reliance can be placed on the label.

AUTOPLASTIC OVARIAN TRANSPLANTATION.

THE number of cases of ovarian transplantation recorded is so limited that every case is of value. In the *Medical Journal of Australia* Dr. J. H. Nattras has reported the following case. A married woman, aged 17 years, was admitted for her confinement to the Women's Hospital, Melbourne, on March 5th, 1911. She had suffered from hip and spinal disease for ten years and had not walked, except with crutches, since the age of 7 years. Menstruation occurred regularly until May 15th, 1910, and then ceased. The right lower extremity was 12 inches shorter than the left and much atrophied. The hip-joint was ankylosed with the thigh flexed and fixed in a position over the middle line. There was a tuberculous sinus over the right trochanter, and scars from healed sinuses were present over the lower lumbar vertebræ and right buttock. The appearance of the abdomen was consistent with pregnancy at term. The fœtus was alive and apparently below the average size, but there was not the slightest engagement of the head in the pelvic brim. Examination per vaginam showed a generally contracted pelvis, especially in the true conjugate diameter, which was 3 inches, and the transverse diameter of the outlet, which barely admitted three fingers. As natural delivery was impossible it was decided to perform Cæsarean section and, in consequence of the tuberculous condition of the patient and her deformities, to sterilise her by transplanting the ovaries. As 294 days had passed since the commencement of the last menstruation the operation was performed without delay. On March 7th, 1911, a full-time female child, weighing 6 lb., was removed. The ovaries were excised and immediately placed in normal saline solution at 98·4° F. Each ovary was incompletely divided longitudinally through its hilum. As much ovarian stroma was cut away as possible with curved scissors, because a transplanted ovary degenerates to an extent directly proportionate to its thickness and density. By sacrificing the fibrous stroma the ovum-bearing part is more easily nourished. Each ovary being thus prepared under saline solution, the sheath was separated from the anterior surface of the left rectus muscle until the outer border of the muscle was free. With catgut sutures the surface of the incompletely divided left ovary was fixed on the muscle border so as to form a sandwich with it. The cut surface of the right ovary was fixed with catgut to the right external oblique muscle about 2 inches from the middle line. Recovery was uninterrupted. The patient suckled the baby for nearly five months, until the first week of August. On Sept. 24th menstruation recommenced and was fairly regular. Sometimes the patient knew she was about to menstruate by tenderness in one of the grafted ovaries, usually in the subcutaneous one. She thought that the ovaries swelled on these occasions. Three and a half years after the operation the subcutaneous graft could be easily felt, and a sickening sensation was produced by palpation. The left ovary, which was placed more deeply, could not be palpated definitely, but a spot could be found pressure on which caused a sickening sensation. This sensation and occasional pain on menstruation seemed to indicate the development of nerves in the graft similar to the development of blood-vessels, which is known to occur. The patient looked well, the uterus was of normal size, and there were no symptoms of the menopause. As an example of successful ovarian transplantation the case is of great interest, but it may be suggested, as is done by Mr. A. N. McArthur in a subsequent issue of the same journal, that sterilisation could have been effected by the much simpler operation of resecting the tubes.

Dr. Henry Lewis Jones, consulting medical officer to the electrical department at St. Bartholomew's Hospital, died at his residence, 143, Harley-street, W., on Easter Day. Dr. Lewis Jones was the best known authority in this country on the electrical treatment of disease; he was a pioneer, and remained in the van. He had been in ill-health for some considerable time, and the recent death of his only son while on active service no doubt hastened his death at the age of 58 years.

THE King has given to Dr. David James Galloway His Majesty's Royal licence and authority to wear the Insignia of the First Class of the Order of the Crown of Johore, conferred upon him by His Highness the Sultan of Johore in recognition of valuable services rendered as physician extraordinary to His Highness.

METROPOLITAN ASYLUMS BOARD.—A three months' course of lectures and demonstrations in hospital administration for the Diploma in Public Health will be given as follows: (1) At the North-Western Hospital, Lawn-road, Hampstead, N.W., by Dr. J. MacCombie, medical superintendent, on Mondays and Thursdays, at 5 P.M., beginning Monday, April 12th; and (2) at the Grove Hospital, Tooting-grove, Tooting Graveney, S.W., by Dr. J. E. Beggs, D.P.H., medical superintendent, on Mondays and Thursdays, at 5 P.M., beginning Monday, April 12th. The fee for the course is £3 3*s*. Cheques should be made payable to the "Metropolitan Asylums Board." Medical men desiring to attend a course of instruction are required, before attending at the hospital, to pay the above-mentioned fee to Mr. T. Duncombe Mann, clerk to the Metropolitan Asylums Board, Embankment, E.C., giving their full name and address.

THE MANUFACTURE OF SALVARSAN PRODUCTS IN ENGLAND AND FRANCE.

WE have received the following communication from the Secretary of the National Medical Research Committee (National Health Insurance Act) :—

In consequence of the outbreak of war the Board of Trade suspended the Patent and Trade Mark of the drugs Salvarsan and Neo-Salvarsan, and, as the medical profession will be generally aware, granted a licence to Messrs. Burroughs, Wellcome, and Company for the manufacture in this country of these preparations, which they sell under the names of Kharsivan and Neo-Kharsivan, and to the Société Anonyme des Etablissements Poulenc Frères, of Paris, for the sale in Great Britain (through the agency of Messrs. May and Baker, Limited) of the same products under the names of Arsenobenzol-Billon and Nov-Arsenobenzol-Billon.

It must be understood that, although the manufacturers have in both instances adopted distinguishing trade names for their preparations, the latter are not merely similar substitutes for, but are chemically identical with Salvarsan and Neo-Salvarsan, differing in no known respect from Ehrlich's original products, either in their final constitution or in the details of their preparation. The proof of such absolute identity is, however, in the case of these substances a matter not only of great importance but of unusual difficulty. Salvarsan is a highly reduced substance. If the reduction, which constitutes one stage of its manufacture, is carried out with insufficient vigour, or if the product is later exposed to the danger of oxidation by contact with air, it is readily contaminated with a much more toxic oxidation product. The water-soluble derivative "Neo-Salvarsan" is even more liable to this defect. As a matter of fact it is impossible, by the most careful procedure, altogether to exclude the presence of the more toxic oxide, and the best specimens, from any source, contain it in the proportion of about 0·5 per cent. The extent of this known contamination can be chemically determined with some degree of accuracy, and it is an obligation resting upon the manufacturer to see that no batch of his product contains it in an unsafe proportion. According to Ehrlich the proportion varies from 0·5 to 0·8 per cent. in good specimens.

If the presence of an excess of this easily recognisable and determinable oxide were the only source of difficulty or danger, a chemical standard of purity, on similar lines to many in the Pharmacopœia, could easily have been defined and enforced for these preparations. Unfortunately there are indications that other toxic products, of unknown constitution, may arise through uncontrollable accidents of preparation. The presence of these is only indicated by the fact that the toxicity of the Salvarsan products cannot be accounted for by the percentage of the known toxic oxide which they contain. While, therefore, the determination of the latter is a necessary safeguard, it can be regarded as a preliminary precaution only, and the final appeal, in the present state of knowledge, must be to animal experiment, the result of which gives evidence of the total toxicity from whatever source it comes.

The Board of Trade licence in both the above cases was therefore granted subject to the condition that all samples of these drugs sold in this country should be submitted to biological tests by an authority approved by the Board of Trade.

In the special emergency created by the war the Medical Research Committee, at the request of the Board of Trade, accepted for the time being the responsibility of directing the biological tests of the Salvarsan and Neo-Salvarsan produced by these English and French firms.

Examples of these products, therefore, cannot be properly sold in this country by Messrs. Burroughs, Wellcome, and Company or by Messrs. May and Baker unless and until samples of the batch of product from which they are taken have been tested under the direction of the Committee and a certificate has been issued by the Secretary of the Committee approving that particular batch for sale.

In view of the public interest which must attend the establishment of so intricate a manufacturing process in England at short notice, and in view also of the great importance to the medical profession and the public of the degree to which success has been attained in the manufacture, it is thought desirable that a general statement should be made of the policy which the Medical Research Committee have pursued in their performance of the public duty which has fallen to them.

When the work of biologically testing samples of these arsenical compounds from other than German sources was undertaken, there was no time for any elaborate preliminary investigation of new methods of biological assay. The public need for an immediate and abundant supply was urgent, and the existing stocks of German production were found to be too low to allow delay.

The Committee entrusted the details of the work to most competent pharmacological workers, who took as a basis for the biological control, supplementing the chemical tests of the manufacturer, the methods and standards which had previously been found adequate in Ehrlich's Institute. It was decided, accordingly, that specimens should be passed as satisfactory, under the official certificate of the Committee, which were not more toxic to mice than the average sample of German manufacture. This decision has already involved the rejection of some samples which exhibited no greater toxicity than some of those previously issued in this country, with Ehrlich's authority, and used therapeutically without adverse result.

In addition, however, to this application in all cases of the official German test, every sample has been further tested by the intravenous injection into a rabbit of a large dose only slightly less than that which may be expected, according to Ehrlich's publications, to be lethal for the animal. The object of this test was to guard against the presence of any immediate toxic constituent which might escape detection when doses were given hypodermically to mice. If, in the performance of this test, any difference had been found to exist as between the English or French products on the one hand, and the original German products on the other, the sample in question would not have been passed for certification and for sale to the public.

It should also be added that in addition to these biological tests which have been imposed as an invariable routine, the Committee have caused experimental assurance to be obtained that both the French and English preparations are equivalent to the German in therapeutic effect. This has been done by a comparison of their relative potencies in curing experimental trypanosomiasis in mice and experimental spirochæte infections in rabbits.

In the opinion of the Medical Research Committee, the experimental work which has been done under their direction has already shown that the problem of the successful manufacture of the Salvarsan compounds in England and France has been solved. By the communication from time to time to the manufacturers of certain findings of the scientific workers, entrusted with the problem by the Committee, assistance has been given wherever possible towards the establishment of fully satisfactory technical manufacturing methods, and the Committee are confident that, so far as the strictest laboratory controls can ensure it, the profession and the public are now receiving from English and French sources compounds fully up to the standard of the best German samples previously sold. It is to be hoped that very soon the quantity of the products so supplied will be as sufficient as their quality.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

The War.

THE interest in the European War is still the prominent feature of all public discussion and activity. The Federal Government proposes to place no actual limit on the number of men sent abroad, and recruiting is proceeding daily at all important centres. No difficulty has been found in providing medical officers, and volunteers are still in considerable excess of the demand. The physique of the men selected is still kept to a high standard. Much public interest has been shown in the provision of motor ambulances for the front. The Australian Women's National League in Victoria has supplied four from a purely women's subscription. The medical profession throughout Australia have equipped two from a general subscription, and the Victorian Bar has offered one to the Defence Department. Similar movements are on foot throughout all the States, and the various Red Cross and relief funds are being added to daily.

Soldiers and Alcohol.

Public attention has been attracted to the indulgence in alcohol by soldiers, and various suggestions are being made. In Victoria deputations of temperance and religious organisations waited on the Premier and asked for earlier closing of hotels. Sir A. Peacock deprecated the idea that as a body the men were over-indulgent. It might be true that some individuals drank too much, but this was not characteristic of the Australian troops. He promised to look into the Licensing Act and do what was reasonable to mitigate drinking to excess by the men, and at the same time expressed the view that the abolition of wet canteens by the defence authorities did not make for sobriety among the troops.

Personal War Items.

Surgeon-General W. D. C. Williams, the Director-General of Medical Service to the Commonwealth military forces, has been appointed honorary Surgeon-General of the British Army.—Mr. F. D. Bird, lecturer in surgery in Melbourne University, who went as a volunteer with the Expeditionary Force, has been appointed consulting surgeon to the Australian forces in Egypt.—Mr. R. Hamilton Russell, who was attached for some time to the Australian Voluntary Hospital at Wimereux, has returned to Melbourne and resumed practice.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

An Easy Mode of Sterilising Material for Dressings.

Professor Weil, of Lyons, has recommended an excellent method of sterilising linen by ironing. From his experiments on baby-linen Professor Weil finds that the temperature at which laundresses used the heated iron is about 150° C. It will cause hydroquinone to melt. But linen is not sterilised every time it is ironed unless it has been previously dampened throughout. The laundress sprinkles the linen before ironing, thus unconsciously fulfilling the conditions desirable for a satisfactory sterilisation. A fire, a flat-iron, some linen, these are all that is necessary to provide a supply of sterilised dressings, and they can be obtained almost anywhere; even in the country one can find plenty of used linen which, in consequence of its greater suppleness than when new, is admirably adapted to make dressings. It is cut into pieces of the required size and folded into compresses of suitable shape. Every house has a flat-iron, and a fire can always be got. Some flat surface is necessary to serve as an ironing board, and it is covered with some thickness of stuff in cushion fashion so as to make the ironing easier. This is covered with linen, which is carefully ironed first, and is left in place forming a sterile surface upon which the dressings can be ironed. It is necessary before sterilising each object to pass the hot iron afresh over the linen covering of the ironing board. The iron may be considered as sufficiently hot when, on bringing it within a few centimetres of the cheek, a heat too powerful to be borne is felt. In ironing it is necessary to touch the linen, wherefore aseptic hands are required, and in addition it is a good plan to paint the tips of the fingers with tincture of iodine. The blue mark caused on the linen thereby is of no consequence in this case. The *sine quâ non* is that the linen should be carefully moistened before ironing—indeed, the principle of moist sterilisation, as in the autoclave, is thus realised. Finally the linen is ironed surface by surface and fold by fold. It is important never to touch the linen save at the corners and always to run the iron over the place that has been touched. If the material is not to be used immediately it should be covered as soon as possible away from the dust in the air. A soldier's mess-tin makes a very good dressing receptable; it is easily sterilised by boiling or heating.

A Mechanotherapy Apparatus.

M. Privat recently showed at the Academy of Medicine a very simple method of constructing a mechanotherapy apparatus. Every medical man knows how to construct a continuous traction apparatus with a weight, a piece of cord, and a pulley. If the point of attachment of this pulley is made mobile by suspending it by a cord from the ceiling, the weight in balancing produces rhythmic tractions passing alternately from maximum to minimum. This apparatus can further be graduated according to the degree of sensibility of the joint. With two pulleys of different diameters it is possible to make five different dispositions, each giving (for the same weight) a different result, which allows diminution or augmentation of the interval between maximal and minimal tractions.

Public Health.

REPORT FOR 1913 OF THE MEDICAL OFFICER OF HEALTH AND SCHOOL MEDICAL OFFICER OF THE ADMINISTRATIVE COUNTY OF LONDON.[1]

PART II.—EDUCATION.

IN an introductory note to this part of the present report Dr. W. H. Hamer gives an account of the further development of school work in the direction foreshadowed in his previous report. Among measures of special importance he refers to the reorganisation of the Council's arrangements for the medical inspection and treatment of school children, the promotion of efforts for the control of infection in schools, and the maintenance of schemes for encouraging personal hygiene and cleanliness.

Medical Inspection and Treatment.

In making provision for the efficient inspection and treatment of school children the numerical strength of the medical inspecting staff must obviously be adequate. The question of the suitability of the candidate for appointment will also require careful consideration. Respecting the latter point Dr. Hamer insists that for the efficient discharge of his duty the school doctor should have received special training in public health. It is imperative, for example, that he should be expert in the detection of conditions inimical to health and in the investigation of infectious outbreaks in the schools under his charge, inasmuch as prompt and decisive action is often required at the school itself in order, *inter alia*, to avoid unnecessary interference with educational work. Moreover, this officer should be thoroughly conversant with the physical and mental development of normal and abnormal children, so that he may be competent to advise in cases of backwardness or retarded development or of other conditions detrimental to educational progress. When medical inspection was first undertaken in London the term of appointment of officers seldom exceeded three years. Consequently the supervision and training of the newly appointed doctors entailed a severe burden on the supervising staff, and frequent changes proved so prejudicial that steps have recently been taken to secure greater permanency and continuity in the work. The inspecting medical staff has therefore been reconstituted. London has been divided into five districts instead of four as formerly, the staff of each district being controlled by a divisional medical officer with the aid of additional permanent and temporary medical assistants. In order to comply with the suggestions of the Board of Education it has been arranged that the permanent medical assistants shall share in the general work of the department, including the inspection and "following up" of defective children, the visitation of treatment centres, and the regulation of open-air schools. General public health supervision is now added to the duties of these officers, including the investigation of infectious disease and the control of tuberculosis among school children.

Centres for Medical Treatment.

During the year under review there has been a large increase in the facilities afforded by the Council for institutional treatment. At the end of the year 34 centres existed, in which 84,350 children were treated, or more than 11,000 in excess of the number treated in the previous year. The reorganisation of the medical staff already referred to has led to extension of the school doctors' work by reinspection in all cases where hospital or other medical treatment has been recommended. During the year the number of such re-inspections is estimated at 150,000. Dr. Hamer testifies to the satisfactory character of the work now in progress, a result that could not have been achieved by a staff previously unskilled in the details of school inspection.

Government Grants.

In the course of 1913 new regulations were issued by the Board of Education providing for the first time for the payment of grants in respect of medical inspection, in addition to those formerly payable in respect of medical treatment. The grant for the year under notice was equal to 46 per cent. of the County Council's total expenditure under this head. In announcing a grant of more than £31,000 the Board expressed their appreciation of the improvements effected in the work of the authority's school medical service and, in particular, their recognition of the extension of facilities for treatment. Moreover, in Sir George Newman's recent report to the Education Department,[2] referring to the medical treatment of London school children under the County Council's scheme, the following sentence occurs: "In any case, the figures clearly indicate the vast amount of benefit that is accruing to the defective school children of London as the result of the Council's organised scheme of medical inspection and treatment."

Public Health Laboratory.

A well-equipped laboratory has recently been established by the County Council which, as part of the public health organisation, has already been found valuable by the medical department. Amongst other uses it frequently affords a trustworthy means of diagnosis in cases of sore throat associated with infectious disease, as well as in doubtful cases of ringworm, favus, and other microbic affections. It has consequently been of great assistance in the detection of possible foci of infection in the Council's schools; in addition to which, specimens are frequently received for bacteriological examination from the places of detention and the industrial schools belonging to the County Council. The number of cultures examined in this laboratory in the course of 1913 has exceeded 2000.

Infectious Diseases amongst School Children.

Scarlet fever.—Compared with the average for the three previous years, scarlet fever showed a considerable increase in London schools.

Measles.—The incidence of measles amongst school children was lower in 1913 than in any of the preceding seven years. Among measures for limiting measles prevalence compulsory notification has been fairly tried, but seldom with success. For protective purposes exclusion from school is now generally confined to children in the infant departments, more than 90 per cent. of the children attacked being below 5 years of age. The severity of attack largely depends on the age of the patient. The younger children usually suffer excessively and are more liable than their elders to complications which may be fatal or may predispose to tuberculosis, ear discharge, or injury to eyesight. Accordingly, if children cannot be prevented from eventually contracting measles, efforts should at any rate be made to protect them from attack in early infancy.

Diphtheria.—Diphtheria prevalence was more marked in London than in the provinces. Of the London attacks notified at all ages more than one-third occurred among school children. Many schools which showed a tendency to spread the infection by contact were kept under constant observation by school doctors, and 2220 cultures were forwarded for examination in the laboratory. True diphtheria germs were identified in 112 cases, whilst a further 212 cultures contained germs not definitely distinguishable from the Klebs-Löffler bacillus. Still unsolved is the difficulty of dealing effectually with bacteriological cases of diphtheria in which the usual clinical symptoms of the disease are not apparent. Further research in this direction is therefore desirable.

Ringworm and favus.—The differential diagnosis between these diseases is by no means easy to make, and the importance of laboratory aids to diagnosis is apparent in the discovery of these otherwise unrecognised cases. Of the 76 cases of favus reported during the past two years no fewer than 63 have been discovered by microscopical examination in the Public Health Department. During 1913 large numbers of specimens of hair have been sent to the laboratory by school doctors for microscopic examination. Out of 3464 specimens submitted ringworm was found in 1979 cases and favus in 57 cases; in 1415 cases no fungus was found. Ringworm involves so much interference with school attendance and with the educational progress of children that it would be a misfortune if treatment by X rays, the speediest known method of cure, were discontinued. Much improvement has recently been effected in the method of applying the X rays. Most of the cases where unsatisfactory results have been recorded date from the early days of that treatment.

[2] THE LANCET, Jan. 9th, 1915, p. 84.

Tuberculosis amongst School Children.

In the routine work of medical inspection special attention is given to the detection of early tuberculosis amongst school children, the object being to place them promptly under the treatment of the School Care Committee. In the schools examined during the year 0·41 per cent. of the children examined were found to be the subjects of pulmonary tuberculosis, and 0·32 per cent. of other tuberculous affections. On the whole it appears that the incidence of tuberculosis in school children varies inversely with the average standard of comfort in the home. The close interrelation of malnutrition with tuberculosis is generally recognised and has been confirmed by recent investigations.

Open-air Schools.

The two open-air schools maintained by the Council have been in operation throughout the winter with uniformly good results to the children's health. Medical inspection of the ordinary elementary schools has abundantly proved the need for additional schools on the open-air principle, but for these it has hitherto been found impossible to obtain suitable sites either north or south of the Thames. Particulars are given of the schools at Birley House and Shooter's Hill and of the defects noted among the children there resident, as well as of the considerable numbers of children returned to ordinary elementary schools because of improvement in their physical condition. Last year's experience of the former school confirms that of the previous six years as to the existence of a large class of delicate children who are capable of mental and physical improvement in such schools. At the Shooter's Hill school, where the average attendance is about 100, so great was the improvement effected by the treatment there received that nearly one-third of the pupils were discharged in 1913 as fit to return to the ordinary elementary schools. Figures are given showing measurements of the height, weight, and chest capacity of the boys and girls respectively. These figures show general amendment, which is also borne out by the increased smartness and intelligence observed in the children. It is frequently stated that after a sojourn at Shooter's Hill school children previously regarded as almost defective mentally had returned completely changed—bright, energetic, and good workers, in strong contrast with their condition prior to entering that institution.

Personal Hygiene and Cleanliness.

In the report for last year the development of the "cleansing scheme" was traced from the purely voluntary work effected in 1902 to the County Council's arrangements of 1912, whereby cleansing centres were established and a large staff of specially trained nurses were appointed. In the year under review nearly 859,000 children were examined, more than 29,000 of whom were found to be verminous. The fact that an increasing proportion of these children are now voluntarily cleansed at home shows that parents are at length beginning to realise the importance of cleanliness to the well-being of their offspring. The scheme for dealing with unclean heads and verminous bodies has been modified so as to accelerate the process of cleansing and to secure closer coöperation with the local authorities in dealing with clothing, &c., in the homes of the children.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last census, 8917 births and 6879 deaths were registered during the week ended Saturday, March 27th. The annual rate of mortality in these towns, which had declined from 20·7 to 19·3 per 1000 in the five preceding weeks, rose in the week under notice to 19·8 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of 1914. During the first 12 weeks of the quarter just ended the mean annual death-rate in these towns averaged 19·5, against a corresponding rate of 20·5 per 1000 in London. The annual death-rate during the week ranged from 6·1 in Lincoln, 9·7 in Leyton, 9·9 in Grimsby, 10·5 in Stockton-on-Tees, and 10·6 in Barnsley, to 26·4 in Salford, 27·5 in West Hartlepool, 28·1 in Northampton, 30·0 in Wolverhampton, and 34·2 in Aberdare.

The 6879 deaths from all causes were 165 in excess of the number in the previous week, and included 695 which were referred to the principal epidemic diseases, against numbers increasing from 511 to 739 in the six preceding weeks. Of these 695 deaths, 397 resulted from measles, 127 from whooping-cough, 70 from infantile diarrhœal diseases, 58 from diphtheria, 31 from scarlet fever, and 12 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·0, or 0·1 per 1000 less than in the previous week. The deaths attributed to measles, which had increased from 207 to 421 in the six preceding weeks, fell to 397, and caused the highest annual death-rates of 3·4 in Croydon, 3·7 in Merthyr Tydfil, 4·1 in Smethwick, 4·4 in Darlington, 5·3 in West Bromwich, 6·0 in Wolverhampton, 7·4 in Northampton, and 9·7 in West Hartlepool. The deaths referred to whooping-cough, which had been 110, 120, and 151 in the three preceding weeks, fell to 127, and included 31 in London, 10 in Liverpool, 6 in Bristol, 5 each in Brighton and Birmingham, and 4 each in Leeds, Merthyr Tydfil, and Aberdare. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 71, 77, and 63 in the three preceding weeks, rose to 70, of which 24 were registered in London, 6 in Birmingham, and 5 in Liverpool. The deaths attributed to diphtheria, which had been 64, 51, and 61 in the three preceding weeks, fell to 58 and included 16 in London, 8 in Birmingham, and 3 in Liverpool. The deaths referred to scarlet fever, which had been 32, 21, and 29 in the three preceding weeks, rose to 31, of which 13 occurred in London, and 2 each in Ipswich and Wigan. The fatal cases of enteric fever, which had been 10, 15, and 14 in the three preceding weeks, fell to 12, and included 5 in London and 3 in Manchester.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5036 to 2730 in the 17 preceding weeks, had further fallen to 2672 on Saturday, March 27th; 301 new cases were admitted during the week, against 298, 275, and 289 in the three preceding weeks. These hospitals also contained 1445 cases of diphtheria, 342 of measles, 57 of enteric fever, 16 of whooping-cough, and 3 of small-pox. The 1935 deaths from all causes in London were 112 in excess of the number in the previous week, and corresponded to an annual death-rate of 22·3 per 1000. The deaths referred to diseases of the respiratory system, which had been 468, 442, and 478 in the three preceding weeks, further rose to 481 in the week under notice, and were 190 above the number recorded in the corresponding week of last year. The deaths from influenza numbered 65, against 48, 54, and 67 in the three preceding weeks.

Of the 6879 deaths from all causes in the 96 towns 224 resulted from different forms of violence and 495 were the subject of coroners' inquests, while 1930 occurred in public institutions. The causes of 51, or 0·7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Manchester, Sheffield, Leeds, Bristol, West Ham, Bradford, Hull, and in 63 other smaller towns. Of the 51 uncertified causes, 10 were registered in Birmingham, 4 each in Liverpool and Preston, 3 in Southend-on-Sea, and 2 each in London, Reading, Stoke-on-Trent, Southport, Darlington, Sunderland, South Shields, and Gateshead.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1290 births and 948 deaths were registered during the week ended Saturday, March 27th. The annual rate of mortality in these towns, which had been 23·2, 20·9, and 20·8 per 1000 in the three preceding weeks, rose to 21·1 per 1000 in the week under notice. During the first twelve weeks of the quarter just ended the mean annual death-rate in these towns averaged 22·4, against 19·5 per 1000 in the large English towns. Among the several towns the death-rate during the week ranged from 13·0 in Coatbridge, 13·7 in Falkirk, and 14·0 in Ayr, to 23·1 in Aberdeen, 25·4 in Kilmarnock, and 29·1 in Dundee.

The 948 deaths from all causes were 12 in excess of the number in the previous week, and included 132 which were referred to the principal epidemic diseases, against 131 and 139 in the two preceding weeks. Of these 132 deaths, 81 resulted from whooping-cough, 21 from measles, 12 from scarlet fever, 10 from infantile diarrhœal diseases, 7 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·9, against 2·0 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had been 91, 87, and 88 in the three preceding weeks, fell to 81, and included 46 in Glasgow, 13 in Dundee, 11 in Edinburgh, and 4 in Kilmarnock. The deaths referred to measles, which had been 21, 15, and 26 in the three preceding weeks, fell to 21, and comprised 14 in Glasgow and 7 in Dundee. The fatal cases of scarlet fever, which had been 9, 13, and 11 in the three preceding weeks, were 12 in the week under notice, and included 6 in Glasgow and 2 each in Aberdeen and in Paisley. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 7, 5, and 6 in the three preceding weeks, rose to 10, of which 5 occurred in Glasgow and 2 in Aberdeen. The deaths referred to diphtheria numbered 7, against 15, 10, and 7 in the three preceding weeks, and included 4 in Glasgow. The fatal case of enteric fever was registered in Paisley. In addition to the above deaths a fatal case of typhus fever was recorded in Dundee.

The deaths referred to diseases of the respiratory system, which had been 264, 215, and 188 in the three preceding weeks, further fell to 186 in the week under notice, but were 75 above the number recorded in the corresponding week of last year. The deaths attributed to violence numbered 34, against 23 and 36 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,212,380 persons at the middle of this year, 651 births and 555 deaths were registered during the week ended Saturday, March 27th. The annual rate of mortality in these towns, which had declined from 27·6 to 24·0 per 1000 in the four preceding weeks, further fell to 23·9 per 1000 in the week under notice. During the first 12 weeks of the quarter just ended the mean annual death-rate in these towns averaged 25·6, against corresponding rates of 19·5 and 22·4 per 1000 in the English and Scotch towns respectively. The annual death-rate during the week under review was equal to 26·8 in Dublin (against 22·3 in London and 21·8 in Glasgow), 21·3 in Belfast, 26·5 in Cork, 34·2 in Londonderry, 20·3 in Limerick, and 11·4 in Waterford, while in the 21 smaller towns the mean rate was 22·4 per 1000.

The 555 deaths from all causes were 3 fewer than the number in the previous week, and included 47 which were referred to the principal epidemic diseases, against 37 and 36 in the two preceding weeks. Of these 47 deaths, 16 resulted from whooping-cough, 12 from measles, 11 from infantile diarrhœal diseases, 6 from scarlet fever, and 2 from diphtheria, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 2·0, against corresponding rates of 2·0 and 2·9 per 1000 in the English and Scotch towns respectively. The deaths attributed to whooping-cough, which had been 10, 12, and 14 in the three preceding weeks, further rose to 16, of which 10 were recorded in Dublin and 3 in Belfast. The deaths referred to measles, which had been 8 in each of the four preceding weeks, rose to 12, and included 4 each in Belfast and Coleraine and 2 in Portadown. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 11, 14, and 4 in the three preceding weeks, rose to 11, of which 6 were registered in Dublin and 3 in Belfast. The 6 deaths attributed to scarlet fever were 2 in excess of the average in the earlier weeks of the quarter, and included 3 in Cork. The fatal cases of diphtheria were recorded in Dublin and Belfast respectively.

The deaths referred to diseases of the respiratory system, which had been 188, 167, and 155 in the three preceding weeks, further fell to 145 in the week under notice. Of the 555 deaths from all causes, 157, or 28 per cent., occurred in public institutions, and 8 resulted from different forms of violence. The causes of 17, or 3·1 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the English towns the proportion of uncertified causes did not exceed 0·7 per cent.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned have been granted temporary commissions as Surgeons in His Majesty's Fleet:—George Murray Heiron, Charles Edward Reckitt, William Whitfield, Marmaduke Fawkes, Hugh Bernard German, William Gifford Wyllie, Harry Aitken Hewat, and John Benjamin Crawford.

The following appointments have been notified:—Staff-Surgeon: G. S. Davidge to the *Sirius*. Surgeon: A. V. J. Richardson to the *Brilliant*.

ROYAL NAVAL VOLUNTEER RESERVE.

Temporary commissions in the Royal Naval Volunteer Reserve have been issued as follows:—Dental Surgeons: Stanley Maddox Gardner, Clementson Glover, Alan Basil Hacking, Roy William List, Frederick William Paul, Edwin Joseph Handford, and Herbert John Corin.

ROYAL ARMY MEDICAL CORPS.

The undermentioned are granted temporary rank whilst serving with the Field Ambulances of the Welsh Division:—As Lieutenant-Colonel: John Edward Henry Davies dated Dec. 2nd, 1914), Major Robert John Richard Cobden Simons, Territorial Force (dated Jan. 9th), and Captain Thomas Price Thomas, Territorial Force (dated Jan. 6th). As Major: William Bickerton Edwards (dated Dec. 2nd, 1914). As Captain: Andrew Woodroffe Anderson (dated Dec. 2nd, 1914) and Edward Llewelyn Parry-Edwards (dated Jan. 30th). As Lieutenant: Frederic Samuel Rowland (dated Dec. 20th, 1914).

The undermentioned Lieutenants to be Captains:—Dated March 30th: Alexander G. Biggam, Roy K. Mallam, William McNaughtan, David T. M. Large, Walter W. Pratt, William F. Christie, Maurice Burnett, Alexander Hood, Edward A. Strachan, Cuthbert J. Blaikie, James H. M. Frobisher, Walter B. Stevenson, John L. Ritchie, David T. Richardson, Owen W. J. Wynne, Christopher M. Ingoldby, Sydney J. Higgins, Gilbert A. Blake, Percy A. With, Cuthbert J. H. Little, Stephen J. Barry, Robert W. Vint, Henry R. L'Estrange, Harold W. L. Allott, Edward P. A. Smith, Robert B. Price, James B. A. Wigmore, John Hare, Robert A. Flood, Eric C. Lang, William V. Corbett, Leopold T. Poole, Thomas H. Balfour, Frank C. Cowtan, Charles C. Jones, Edward V. Whitby, Edmund U. Russell, Robert G. Shaw, Norman W. Stevens, Richard B. Phillipps, Alexander L. Urquhart, Noel T. Whitehead, James C. Sproule, Avenell F. C. Martyn, George F. Allison, Robert C. Carlyle, John E. Hepper, Arthur A. M. Davies, Leslie Dunbar, Henry F. Panton, Henry Beddingfield, D.S.O., Frederick C. Davidson, Stanley D. Large, Cyril Helm, Humfrey N. Sealy, Albert Jackson, Edward C. Beddows, George E. Dyas, Conyngham V. Thornton, John Rowe, William P. Croker, Arthur B. H. Bridges, Aubrey G. Brown, Percival D. Warburton, Robert Hemphill, Summer H. Smith, Ernest W. Wade, Bernard Woodhouse, William K. Morrison, Edgar Percival, Henry C. D. Rankin, Treffry O. Thompson, Stanley J. Linzell, Lewis R. Shore, Allan Watson, Norman V. Lothian, John G. Gill, Sidney M. Hattersley, John W. C. Stubbs, Arthur J. A. Menzies, John Fitz G. Gwynne, Thomas F. P. Breen, David C. G. Ballingall, Herbert G. Winter, James M. Evatt, Francis G. Thatcher, William P. Mulligan, Gerard P. Selby, John G. Butt, Neil Cantlie, Edward A. P. Brock, Percival T. Priestley, Edward Phillips, Spence D. Reid, Peter J. Ryan, Barcroft J. L. Fayle, and Evelyn A. Sutton.

Temporary Lieutenant Claude W. S. Saberton relinquishes his temporary commission on account of ill-health (dated March 17th).

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned Lieutenants are confirmed in their rank:—Eric S. Mawe, Edward W. Mann, and Sydney W. Lund.

TERRITORIAL FORCE.

Royal Army Medical Corps.

1st Home Counties Field Ambulance: Lieutenant Charles Killick to be Captain (temporary).

2nd Home Counties Field Ambulance: Captain Antony A. Martin to be Major (temporary).

2nd East Anglian Field Ambulance: Lieutenant James Arthur, from Attached to Units other than Medical Units, to be Lieutenant.

1st West Lancashire Field Ambulance: Surgeon-Captain James Wood, from 5th Battalion, The Loyal North Lancashire Regiment, to be Captain.

2nd London (City of London) Field Ambulance: Lieutenant Horace G. L. Haynes to be Captain, and William Travers Homan to be Lieutenant.

2nd Lowland Field Ambulance: Major William Bryce, from 1st Lowland Field Ambulance, to be Major.

3rd Lowland Field Ambulance: Captain James W. Keay to be Major (temporary).

1st East Anglian Field Ambulance: Transport Officer and Honorary Lieutenant Frederick Harris resigns his commissions.

3rd London (City of London) Field Ambulance: Major George L. L. Lawson to be Lieutenant-Colonel (temporary).

6th London Field Ambulance: William Henry Dickinson to be Lieutenant.

2nd Northumbrian Field Ambulance: Clifford Crawshaw Pickles (late Lieutenant, 5th Battalion, Alexandra, Princess of Wales's Own (Yorkshire Regiment), to be Captain (temporary).

2nd Wessex Field Ambulance: Lieutenant Henry W. Spaight resigns his commission on account of ill-health.

3rd East Anglian Field Ambulance:—The undermentioned to be Lieutenants: Alexander Cuffe and Edward Knox Goodwin.

1st East Lancashire Field Ambulance: Lieutenant Henry E. Fox, from Attached to Units other than Medical Units, to be Lieutenant.

3rd South Midland Field Ambulance: Captain Charles Corfield, from Attached to Units other than Medical Units, to be Captain.

1st Southern General Hospital: Eric Walter Assinder to be Captain (temporary).

South Midland Casualty Clearing Station: William Albert Higgins to be Lieutenant.

1st London (City of London) Sanitary Company: Henry Holroyd to be Lieutenant.

West Riding Divisional Sanitary Section: Surgeon Captain Harold F. Horne, from the 5th Battalion, The York and Lancaster Regiment, to be Captain.

Attached to Units other than Medical Units.—Captain John Hobbs is seconded. To be Captains: John Alban Davies (late Captain, 7th (Merioneth and Montgomery) Battalion, The Royal Welsh Fusiliers) and Lieutenant Oskar Teichmann. To be Lieutenants: Lieutenant Alfred H. Bell, from 5th London Field Ambulance, Gerald Wetherell Capron Hollist (late Surgeon, Royal Navy), Reginald Devereux Moore, Charles Nyhan (late Lieutenant, 3rd Battalion, The Monmouthshire Regiment), and Berkeley Noel Ash.

THE NATIONAL INSURANCE ACT.

Exempt Persons.

DRAFT regulations, dated March 16th, 1915, have been issued to deal with the limited benefits to be enjoyed under the Insurance Acts by "exempt persons"—i.e., by those who on account of their having means of livelihood independently of their wages from their employers are allowed exemption from contributing to the National Insurance Funds. Employers, it will be remembered, pay the same contributions for exempt persons as for others. Under the new regulations, and subject to the restrictions and conditions prescribed by them, exempt persons will enjoy medical benefit and sanatorium benefit, described in the regulations as "the benefits," an exempt person in respect of whom not less than 20 weekly contributions have been paid being entitled to apply to the Commissioners, and to enjoy the benefits, subject to the regulations being otherwise satisfied, six weeks later. An exempt person who does not so apply, but for whom 20 contributions have been paid, becomes entitled at the commencement of the next benefit period after that in which the twentieth payment on his behalf was made, and provision has necessarily had to be made for those cases in which broken periods of contribution and other circumstances have to be taken into consideration. Contributions out of the Exempt Persons Fund, which is instituted as a separate fund, are to be made to the General Medical Benefit Fund, the General Medical Benefit Administration Fund, and the General Sanatorium Benefit Fund.

Complaints against Medical Practitioners in London.

The reports of subcommittees laid before the London Insurance Committee at its recent meeting contain a good deal of information as to the practical working of the Insurance Acts in the abnormal circumstances created by the war. The report of the Medical Service Subcommittee upon complaints against medical practitioners upon the panel for the County of London commences with a question arising out of an incident which took place at the end of November, and discloses nothing of a serious nature with regard to the supply of medical treatment in the metropolis. Among ten cases investigated three complaints referred to the same practitioner, and of the remaining complaints only two are found to be wholly or partly justified. One of these related to the conduct of a practitioner who declined to visit a patient when sent for, on the ground that he could not quit his surgery at the time. The patient was thus left without medical attention for nearly two days while suffering from a broken leg. The practitioner pleaded that he was ill and had been unable to obtain a locum-tenent. He had also apparently been under the impression that he was not required to provide treatment in cases of accident, and had so informed the patient's messenger, and he had given the messenger a bottle of liniment, with directions, without having seen the leg, which he had been told was broken, and which in fact was broken. The subcommittee found the complaint of neglect to be substantiated, and recommended severe censure for the practitioner. He was required to make provision for a deputy to act on his behalf when unable to attend his patients personally, and his conduct in prescribing without having seen his patient was made the subject of a separate resolution.

Excessive Prescribing and London Practitioners.

The Panel Committee (London) reporting upon cases submitted to them for investigation by the Pharmaceutical Committee, and relating to drugs prescribed in May, 1914, stated that in the case of four practitioners on the panel the cost of drugs and appliances was in excess of what was reasonably necessary for the adequate treatment of their patients; that in the case of three practitioners there was no such excess; that in the case of four others they were unable to come to a decision upon the materials before them. The consideration of these last was therefore postponed. In the case of seven others circumstances prevented the committee from making an investigation.

Obituary.

SIR JOHN LENTAIGNE, F.R.C.S. IREL.,

PAST PRESIDENT OF THE ROYAL COLLEGE OF SURGEONS IN IRELAND.

THE death of Sir John Lentaigne occurred suddenly at his residence in Dublin on March 30th in his sixtieth year. He had been feeling unwell for a few days, but thought little of it, and was persuaded with difficulty to remain in bed on the morning of his death. Early in the afternoon, while talking with two of his colleagues, he suddenly expired. He had been sorely tried a few months ago by the loss of one of his sons at the battle of the Aisne. The lad, a lieutenant in the Connaught Rangers, who had just entered the service, was first reported "missing," and it was not until after some weeks that the fact of his death was ascertained. The anxiety and grief made an indelible mark on his father's health. Only a few weeks ago Sir John Lentaigne suffered a further loss in the death of his brother.

Sir John Lentaigne was the grandson of a French *émigré* of good family who settled in Dublin at the time of the Revolution and became a prominent medical practitioner. On account of his nationality he was chosen to attend Wolfe Tone in prison in his last illness. Lentaigne's father was a Government official in Ireland, and was knighted for his public services. John Lentaigne, born in Dublin in 1855, was educated first at Clongowes College and later at Vannes in France, and then entered Trinity College. He received his medical education at the Catholic University School of Medicine. He graduated B.A. of Trinity College in 1880, and received the licences of the Royal Colleges in the following year. In 1886 he was admitted a Fellow of the Royal College of Surgeons in Ireland. Having been for a short time assistant surgeon to the Richmond Hospital, he became one of the visiting surgeons to Jervis-street Hospital in 1883, and four years later he left there for the Mater Misericordiæ Hospital, where he worked regularly up to the time of his death. He was for many years consulting surgeon to the Royal Hospital for Incurables, and also one of the Lord Chancellor's Visitors in Lunacy. He was surgeon to the household of successive Viceroys for the past 18 years. For 15 years he was a member of the Council of his College, and in 1908 he was elected President. In 1910 he was knighted.

Sir John Lentaigne's reputation as a surgeon was high. He made no claim to great originality, but his work bore the mark of thoroughness and sound experience. He took infinite pains to do the best for his patients, and the most tedious case never exhausted his interest. In his early days, when antisepsis was still little understood and asepsis unknown, he attracted attention and even astonishment by his rigorous methods. He did well in private practice. His family position, his ability, and his charm of character combined to make his career successful. No stress of work, however, was allowed to distract him from the due performance of his hospital duties. Sir John Lentaigne's character and manner were singularly attractive. Until within the last few months, when sorrow tried him, he seemed to be of those who never grow old. He had the *joie de vivre* of a boy, and he had also the frankness and straightforward simplicity of a boy. Success did not spoil him. To his brother practitioners he was always the honourable and kindly comrade, to whom professional jealousy was a thing unknown. In private life he was the soul of geniality, but it was the geniality that rests on a strong foundation of character. In Lentaigne's death not only the Dublin school of surgery but the medical profession have lost a man of outstanding character. His friends miss one of the most lovable of their circle.

BERNARD ROTH, F.R.C.S. Eng.

Mr. Bernard Roth, whose death at the age of 63 we briefly announced in our last issue, was the eldest son of the late Dr. M. Roth, of Wimpole-street, W. After obtaining his M.R.C.S. in 1874 he became house surgeon at University College Hospital, and also studied at Brussels, Paris, Vienna, and Berlin. In 1875 he took the L.S.A. and the M.D. Brux., and joined his father in orthopædic practice, being particularly interested in the treatment of lateral curvature of the spine. In 1878 he married Anna Elizabeth, third daughter of the late Right Hon. John Bright, P.C., M.P., of One Ash, Rochdale, and in the same year obtained the F.R.C.S. Eng. From then onwards he took a leading place among orthopædic surgeons, and devoted his energies to introducing to the medical world a more rational method of treating lateral curvature than was then in use. He was particularly opposed to its treatment by mechanical supports, and through his writings and demonstrations did much to open the eyes of his professional brethren to the harmfulness of such methods.

In 1888 he was elected a corresponding member of the American Orthopædic Association, and in the following year published "The Treatment of Lateral Curvature of the Spine," a second edition of which he brought out ten years later. In the treatment of other orthopædic conditions he was much influenced by his friendship with the late H. O. Thomas, of Liverpool, and frequently attended Thomas's Sunday morning clinics. At these Thomas saw patients at his house free of charge, and his rooms were thronged with scores of patients waiting for his opinion and advice. He was thus one of the first surgeons to become expert in the application of Thomas's splints, now so universally in use. He carried on his practice daily in both London and Brighton for 27 years, travelling by the midday train between the two. At Brighton he held the posts of orthopædic surgeon to the Royal Alexandra Hospital for Children and surgeon to the St. John's Convalescent Home.

In his later years he was much interested in numismatics, and besides other papers published in 1910 a monograph on the Hiberno-Danish coins. At the time of his death he was a Vice-President of the British Numismatic Society and of the Royal Numismatic Society, and a Fellow of the Society of Antiquaries. He also occupied himself with magisterial work, being a J.P. for Brighton (1892), a J.P. for Middlesex (1905), and a Visiting Justice, H.M. Prison, Pentonville.

He leaves a wife and two children, a son and daughter, the former of whom, Paul Bernard Roth, follows his father's profession.

JOHN VINRACE, M.D. St. And., M.R.C.S. Eng., L.S.A.

Dr. John Vinrace died at his residence, "Denehurst," Oxford-road, Moseley, on March 12th, at the age of 81. The eldest son of the late Mr. Luke Vinrace, of Ashby-de-la-Zouch, he went to Birmingham in 1851, when he was apprenticed to a medical man and studied at the old Sydenham College, also acting as indoor surgical assistant at the General Hospital. In 1855 he qualified as M.R.C.S. Eng. and L.S.A., and two years later graduated as Doctor of Medicine at the University of St. Andrews. He first started practice in Moseley, but later he entered into partnership at Birmingham. He returned to Moseley some 15 years ago, when he retired. He was one of the oldest and most respected practitioners in Birmingham.

Correspondence.

"Audi alteram partem."

THE DEARTH OF DOCTORS.

To the Editor of The Lancet.

Sir,—Day by day the seriousness of the situation created by the war is deepening, while with those best fitted to judge the demand for more and more doctors seems as steadily to be increasing. Are we then to go on muddling over the question of how best to provide for the inevitable emergency, or shall we take decided steps to deal radically with the situation? Yeoman service has been done by Dr. N. Walker and the Scottish Committee in the interests of the profession as well as of the public at large. But, all the same, it must be allowed that these public-spirited gentlemen have been able to do but little to meet the undoubted dearth of doctors, the deficiency affecting not only the present but the future supply of medical practitioners.

To deal adequately with the position there is only one way of going to work, and that is to revert to the old four years' curriculum. There need be less reluctance against the apparent reduction of the standard of qualification, when it cannot be denied that the change made less than 30 years ago has failed to meet the paramount argument for extending the course of study—i.e., the provision for an extra year to be solely devoted to *practical* bedside work—a result which the change has notoriously not effected. With a sufficiently strict final examination there need be no fear, any more than was the case 30 years ago, of the standard for admission to the Register being degraded to an injurious extent, while the expense of medical education would be lessened. Above all, the change would result in an annual addition of 20 per cent. to the roll of diplomates.

I have just been told of the case of a candidate for the B.D. degree in one of our Scottish Universities who has joined Kitchener's army. Although he is short by a year of completing his curriculum he is to be allowed to sit for his degree. If he be fortunate enough to pass will his fellow graduates think the less of him? War excuses many things which are then a glory and not a disgrace.

I am, Sir, yours faithfully,
WILLIAM BRUCE, M.D. Aberd.,
Late Member of the General Medical Council.
Dingwall, N.B., March 30th, 1915.

THE "ELIZABETH ROSS" BED.

To the Editor of THE LANCET.

SIR,—To those who have read about the terrible struggle against disease and the efforts made to succour the wounded in Serbia at the present time, nothing can have appealed more strongly to public sympathy than the heroic action of the late Dr. Elizabeth Ross, Tain, who added to the glorious record of the medical profession in this terrible war by giving her life to save that of others. It has been felt that in this town, so closely associated with her and her family, some memorial of such self-sacrifice should be set on foot, and that nothing could be more fitting than the establishment of a bed in the hospital at Kragujevatz, where she died. It is hoped that this scheme will appeal not only to those who knew her personally, but to a much wider public, who will welcome an opportunity of showing their appreciation of her heroic action.

Many of us are debarred from active service either in battle-field or field hospital, but we can all "do our bit" by giving to such schemes as this; and surely no more fitting memorial could be raised to this brave woman's memory than one calculated to benefit the country where she laid down her life and where the need at the present time is such a crying and terrible one. Her brothers and sisters of the medical faculty will doubtless be glad to "place a stone on the cairn" of one who has added glory to the noble records of their profession and sacrificed her life in the execution of its duties.

Anything collected over the sum required will be used either in the establishment of a second bed, or in some way to provide medical or surgical comforts to alleviate the terrible distress in Serbia, which Dr. Ross gave her life to help.

Messrs. Wallace and Fraser, Tain, have kindly opened a list for local subscriptions; and donations, large or small, will also be gratefully received and acknowledged by any of the undersigned.

Yours faithfully,
E. K. MACKENZIE, M.D. Aberd.,
Shandwick House, Tain.
(Mrs.) C. IRWIN SMART,
Drynoch Lodge, Tain.
SUTHERLAND M. ROSS,
Woodbine, Tain.
Tain Ross-shire, N.B., April 5th, 1915.

STOMACH *V.* HEART IN RELATION TO PRÆCORDIAL PAIN AND SUDDEN DEATH.

To the Editor of THE LANCET.

SIR,—Mr. Walter Verdon's letter in THE LANCET of April 3rd bears out in many ways one's own personal observations in relation more especially to intercostal pain and heart disease. His contention, as I read it, is that segmental neurosis of that area of the cord which more immediately subserves the regions in the neighbourhood of the heart itself predisposes to anginal attacks, and, similarly, neurosis in other regions may favour spasmodic alimentary disorders. Such a neurosis may be secondary, I take it, to cardiac trouble, but not necessarily so. In a case I had recently under observation the relation of the pain or algesia to the frequent true anginal attacks from which she suffered could with difficulty be explained by any means other than some such segmental neurosis. This patient, who had well-marked aortic incompetence, had from day to day definite areas of deep and superficial intercostal tenderness, varying in site, as Mr. Verdon observes, from day to day, though at times certain intercostal areas, particularly the fourth, would show algesia at exactly the tender spots peculiar to such nerves—namely, near the vertebra, in the axillary line, and near the sternum respectively. Very occasionally she would be free from such areas. In one such phase this patient, in my presence, had a definite anginal attack relieved after a few minutes by amyl nitrite. Afterwards there was not the slightest tenderness to be made out, contrary to what one ought to expect. The suggestion in such a case was that there was a segmental neurosis or possibly a definite radiculitis (the Wassermann was positive), and that this in the main predisposed to her attacks, which were exceptionally numerous. No stomach symptoms were ever present in this case. She died suddenly a few weeks ago.

The whole question of pain and cardiac disease requires more careful investigation than it has yet received.

I am, Sir, yours faithfully,
Manchester, April 4th, 1915. C. EDGAR LEA.

LONDON (ROYAL FREE HOSPITAL) SCHOOL OF MEDICINE FOR WOMEN (UNIVERSITY OF LONDON).—Dr. F. Wood-Jones, lecturer and head of the department of anatomy, has been granted the title of professor of anatomy in the University of London. The title of reader in pharmacology in the University of London has also been conferred on Dr. Fred Ransom, lecturer and head of the department of pharmacology. The Rose Neville scholarship of £150 a year for four, five, or six years, the Mabel Webb research scholarship of £30 for one, two, or three years, the St. Dunstan's exhibition of £60 a year for three or five years, the Mabel Sharman Crawford scholarship of £20 a year for four years, and the Isabel Thorne scholarship of £30 will be awarded during the summer term. Full particulars can be obtained on application to the secretary. Mr. A. G. R. Foulerton has been appointed lecturer in public health in succession to Professor W. J. Simpson, resigned. The Duchess of Marlborough has accepted the office of honorary treasurer of the extension fund, and Miss Edith Calkin, B.A., has been appointed organising secretary of the fund.

CHARGE OF DISPOSAL OF A BODY.—At the recent Galway Assizes, before Lord Justice Ronan, the Rev. Paul Burrus, Superior of Moyne Park Hospice for Infirm Clergymen, was found "Not guilty" of the charge "that he on Dec. 28th, 1914, having the custody of the dead body of the Rev. John Keane, who had died under circumstances which had rendered the holding of an inquest necessary, did dispose of the body with intent to prevent the holding of an inquest." It appeared from the evidence that on the morning of Dec. 26th Father Keane was found in the yard of the hospice in a dying condition, and that he died a little later. He had been of intemperate habits and rather infirm, and had been locked into his room the previous night by Father Burrus. There was reason to believe that he had fallen from his window. No death certificate was given, the medical officer to the institution being informed merely that Father Keane had died rather suddenly. Similar information was given to the police when an officer entered to make inquiries. In defence it was urged that the accused did not act with the intention of preventing the holding of an inquest. He was a foreigner who was probably imperfectly acquainted with English law and customs.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE Fund during the fortnight that has elapsed since we reported upon its progress has received notable accretions.

The large local fund collected in Manchester has now been paid in to the treasurer, making an addition to our resources upon which an influential Manchester committee and Dr. E. M. Brockbank, the energetic secretary, may well be congratulated. Handsome subscriptions have reached the treasurer from Canada and New Zealand, while the funds in the Birmingham and Newcastle districts continue to grow.

The second subscription list of the Scottish Fund is published this week, and shows a total of over £1000.

MANCHESTER AND DISTRICT.

A total of £588 17*s.* 6*d.* has been received, including £104 11*s.* from the pharmacists. The individual subscriptions have all been acknowledged in the press. Any further contributions should be sent direct to London, as this local fund is now closed.

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd. £9700 had passed into the treasurer's hands by Tuesday last, the sum not including the Scottish and Irish Funds.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge the receipt of surgical instruments kindly contributed by Mr. T. F. Blaker, of Brighton, and by Messrs. Claudius Ash, Sons, and Co., Broad-street, W.C.

AT a meeting of the council of the Hampstead General and North-West London Hospital held last Wednesday Mr. Conrad W. Thies, who was present by invitation, received formal thanks for his voluntary help during the absence of the late secretary, Mr. A. E. Thomas, who was killed in the war, and pending the appointment of a successor. The council passed a resolution acknowledging the gratitude of the charity to Mr. Thies for his great assistance, and at the same time begged his acceptance of a gold watch, with suitable inscription, as a slight token of their appreciation of his services during their time of difficulty.

The War.

THE NEED FOR MEDICAL OFFICERS IN THE ARMY: A STATEMENT BY SIR ALFRED KEOGH.

AT a meeting of the Special Committee of Chairmen of Standing Committees of the British Medical Association, held on Thursday, April 1st, Mr. T. Jenner Verrall, chairman of Representative Meetings, presiding, Sir Alfred Keogh, Director-General of the Army Medical Service, was present upon invitation and made an important statement upon the need by the army of more medical officers.

The civil medical profession, he said, had given the army so much generous and self-sacrificing assistance since the outbreak of the war that he regretted to be compelled to make further demands on it. But it was necessary to look ahead and make adequate provision to safeguard the health of the home army when the Expeditionary Force was increased in strength to such an extent that every commissioned medical officer fit for active service would be required for service on the continent. It was anticipated that this increase would take place in the course of the next three or four months, so that the call on medical resources was urgent. Sir Alfred Keogh suggested the following means by which the civil practitioner could come to the aid of the army:—

Whole-time Service.

1. I would urge all those who are under 40 years of age and who are fit for active service to apply for temporary commissions in the R.A.M.C. if their civil obligations will allow them to do so. Such men would have an opportunity of seeing active service on the continent or elsewhere where we have fighting armies. We are especially in need of young general practitioners who are willing to go anywhere and do anything in the way of duty with troops or with medical units.

There are also vacancies for men who have specialised in surgery, bacteriology, medicine, X ray work, and ophthalmic surgery. They would probably eventually be appointed to the large hospitals of 1040 beds each which are being fitted out for service with the Expeditionary Force, but they would be required to do a certain amount of work in a military hospital in this country first, so as to familiarise them with the routine of a military hospital.

2. Men over 40 years of age are not being sent abroad at present, but their services would be of the greatest value to the military authorities in this country, and many of them would probably go overseas for hospital work later on.

Part-time Service.

So much for men who can offer themselves for whole-time and general service, and who are therefore eligible to receive temporary commissions. We now come to men who, on account of age or health, or local obligations, are unable to accept these larger responsibilities. I will divide these into three classes:—

1. Those who can give so many hours a day to military work and give a certain fixed time on each day. These men would be a great help in doing work in military hospitals, seeing men in combatant units reporting sick with minor ailments, and looking after the sanitation of camps, barracks, and billets.

2. Men who could not devote a specific time to military work, but who would be willing to attend

the wives and children of officers and soldiers as part of their general practice at good rates of pay.

3. Men who could arrange to help the neighbouring practitioners who have undertaken military duties, and who would do so without encroaching on their practices, and under terms which would have to be settled by mutual agreement.

It will be seen that every medical man in the country can "do his bit" to help the Government to bring this great war to a successful issue, and from our previous experience we can trust them to respond generously to the appeal we are now making to their patriotism.

A MOTOR OPERATION THEATRE.

A highly convenient operating theatre contrived within a motor wagon has been designed by Captain G. H. Colt, R.A.M.C., assistant surgeon to the Royal Infirmary, Aberdeen.

The chief points in connexion with this motor operation theatre are that it can be easily taken wherever it is required, that its dimensions are reasonable, that it can carry all its personnel, and that its price is not high. The chassis is of the commercial vehicle type, 20–30 h.p., the wheel base being 11 ft. 6 in.; the body is 9 ft. 6 in. long, 6 ft. 6 in. wide; the cab is 3 ft. 6 in. long, 6 ft. 6 in. wide; the height of both is 7 ft. over all, and the weight carried, including five persons, is about 2⅛ tons, suitably arranged as regards steering facilities. A clear space of at least 2 ft. 9 in., and more if required, is available as a stretcher-way.

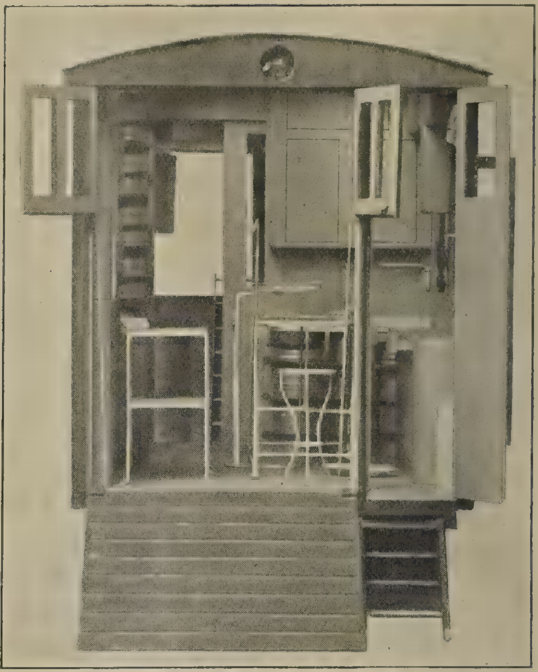

FIG. 1.—Motor operation theatre. Back view.

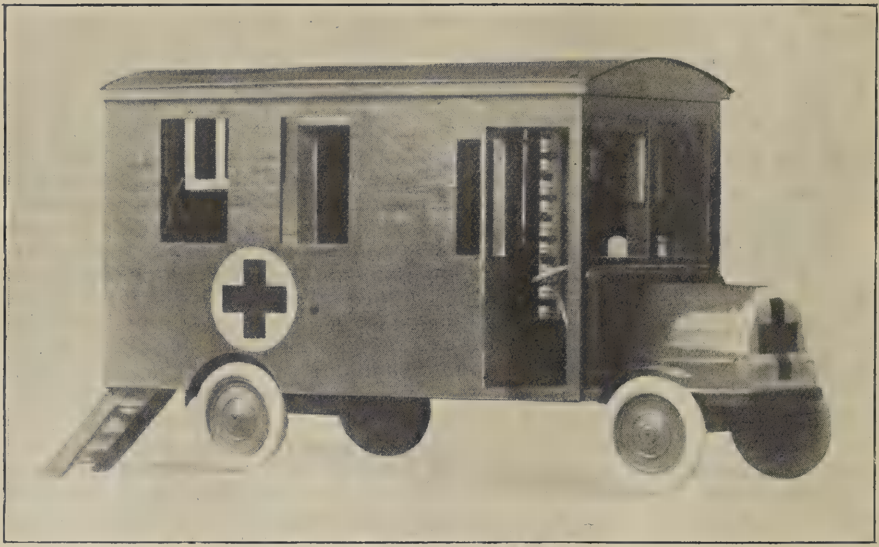

FIG. 2.—Motor operation theatre. Side view.

All boiling and sterilising and drying of washing is done in the cab (or partly outside the theatre) by paraffin burners. The cab is separated by a sliding door from the body of the theatre, thus eliminating phosgene gas, a most important point as regards the efficiency of the personnel. Cold sterile water is obtained in the body of the theatre either by tabloid hypochlorite in 15 minutes or by filling the four vessels from the boiler. The storage room is 34 cubic feet, providing for, say, 60 towels, 15 gowns, wool, gauze, bandages, and instruments. In addition a minimum of 16 full-sized drums, shelves, two drum stools containing plaster of Paris, and a trolley are provided. Seven cubic feet of space are available under the operation table if required. Two 20-gallon water-tanks are carried.

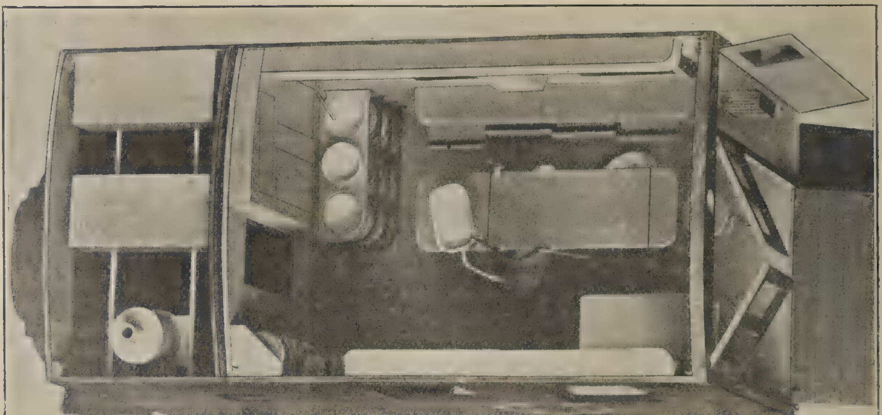

FIG. 3.—Motor operation theatre seen from above.

Electric light can be run for six hours off accumulators. A minimum time of 15 minutes is available for recharging off the engine between operations if required. Ventilation is by windows and an electric fan, causing an indraught of filtered air. Closely fitting flanges to the windows keep out dust, and the tail board is arranged ingeniously so that the outer surface is always outside and dirt is not tipped into the theatre when it is closed up. The back of the car during travelling is covered by American cloth.

Washing, drying, and sterilising are provided for, and so long as supplies arrive regularly the theatre can be kept in constant use to serve casualty clearing stations and to deal with cases of grave abdominal injury, head cases, and large amputation or wound cases. It is not suggested that it should be used for any case that can be removed without risk of further complications ensuing or of pain and shock.

The cost of the theatre is £1100, the chassis costing £600, the body about £200, and the electrical fitting £70, leaving £230 for stores, fittings, and instruments, a sum which need not be spent or can be exceeded.

MENTIONED IN DISPATCHES.

The following names have been added to the list of officers recommended for gallant and distinguished service in the field in the dispatch published in the *London Gazette* on Feb. 17th (see THE LANCET, Feb. 20th, p. 406): Major S. L. Cummins, M.D., R.A.M.C., Captain C. G. Browne, R.A.M.C., and Lieutenant (temp.) G. W. Milne, M.D., R.A.M.C.

In the same list, as previously published, the following corrections are notified with reference to the officers of the Royal Army Medical Corps: Lieutenant (temp.) J. B. Mathews should read Lieutenant (temp.) J. B. Matthews; Lieutenant R. B. Philippo should read Lieutenant R. B. Phillipps; and Lieutenant R. E. Pirrie, M.B. (killed in action), should read Lieutenant R. E. Porter, M.B. (killed in action).

THE CASUALTY LIST.

Since our last issue the casualties reported in our Expeditionary Force include the names of Lieutenant E. Stratford, R.A.M.C., and Lieutenant A. N. Smith, R.A.M.C., both wounded.

THE WATER-SUPPLY OF THE BELGIAN ARMY.

A representative of the Belgian Soldiers' Fund writes on the problem of the water-supply of the Belgian army. Owing to the floods the water, obliged to filter through land soaked in blood and strewn with dead, is in a dangerous condition. In a few weeks the fierce sun will be pouring its rays on a devastated country. A rapid advance of the allied troops is expected, when the forced marches may cause urgent thirst and the tired men, unable to resist the temptation, will drink at the roadside dyke. The terrible conditions that exist in Serbia are due mainly to lack of sanitary organisation in the earlier months of the war. Belgium has no lack of willing men, but does lack funds to place the necessary arrangements at the service of the army and the Government to keep a permanent supply of pure water always at hand till danger is passed. The Belgian Soldiers' Fund has acquired 100 portable 50-gallon boilers complete with pony and harness which are being delivered now, but what is that among so many? As the boilers take a week or two to manufacture the order must be given at the earliest possible date. The Belgian Soldiers' Fund deals entirely with providing food comforts, clothing, and pure water for the Belgian Army and for the widows, orphans, and families of their soldiers. All consignments are made direct to M. de Broqueville, Minister of War. Cheques should be made out to the "Belgian Soldiers' Fund" crossed on Lloyd's Bank and addressed to the Secretary, 17–19, James-street, Oxford-street, London, W.

THE MEDICAL PLIGHT OF SERBIA.

The urgent appeal of Serbia for medical officers to attend the Serbian wounded, preferred through Sir Lomer Gouin, Premier of the Province of Quebec, by the Serbian Royal Legation in London, has resulted in the following Canadians volunteering:—

Dr. Albert Paling, Winnipeg; Dr. J. M. Casserly, St. Thomas, Ont.; Dr. W. J. McAllister, Calgary, Alberta; Dr. A. W. M. Leclair, Letellier, Man.; Dr. O. S. Waugh, Winnipeg; Dr. D. C. Hart, Kipling, Sask.; Dr. Arthur Macaan, Birtle, Man.; Dr. R. L. Hutton, Rosthern, Sask.; Dr. J. Hetherington, Carievale, Sask.; Dr. Thomas H. Smith, North Sydney, N.S.; Dr. James Peake, Winnipeg; Dr. W. A. Dymond, Winnipeg; Dr. Alex. Osmanley, Toronto; Dr. W. P. Mackasee, Springhill, N.S.; Dr. O. A. Cameron, Stratford, Ont.; Dr. A. H. Bowen, London, Ont.; Dr. D. E. Scott, London, Ont.; Dr. J. V. Brandon, Winnipeg; Dr. L. Zealand, Winnipeg; Dr. J. Baxter, Chatham, N.B.; Dr. G. Degrys, Abenakis Springs, Que.; Dr. Alfred Whitmore, Cabri, Sask.; Dr. V. Bourgeault, Marcelin, Sask.; Dr. P. E. Lavoie, Marcelin, Sask.; Dr. C. M. Keiller, London, Ont.; Dr. G. E. Duncan, Vernon, B.C.; Dr. M. F. Lucas, Dryden, Ont.; Dr. J. Murray, Winnipeg; Dr. P. A. Guay, South Shipshaw, Que.; Dr. E. E. Robrabough, Sanford, Man.; Dr. B. A. Hopkins, Blaine Lake, Sask.; and Dr. J. B. McKay, Kitscoty, Alberta.

Several nurses have also volunteered for the Serbian service.

The third and fourth units of the Serbian Relief Funds Hospitals left London on April 1st. The third unit, Mrs. St. Clair Stobart's Hospital, is staffed almost entirely by women. There are 16 nurses, 15 women orderlies, 7 women members of the medical and surgical staff, besides 6 male orderlies and the treasurer. Its destination is Salonica. The fourth unit, the British Farmers' Hospital, under the administration of Mr. L. M. Wynch, C.I.E., has a tent hospital to contain 300 beds, with baths, ice plant, and everything requisite for serum treatment. It has four medical men, a secretary, a matron, 18 nursing sisters, 13 female and 4 male orderlies, and a dispenser, and its destination is Skoplje, where there are said to be some 3000 cases of typhus fever.

THE PRINCESS CHRISTIAN HOSPITAL TRAIN.

The Princess Christian Hospital Train is due entirely to the initiative and energy of Her Royal Highness, by whom also the necessary funds have been raised. It is the successor of the train which, under the same name, was sent to South Africa in 1899. Sir John Furley and Mr. William J. Fieldhouse, who designed the latter train, are responsible for the present one also. The difficulties in the present case were increased by the necessity for consulting different bodies. The War Office laid down that hospital trains should accommodate 400 patients; the French railway engineers required all questions relating to under-carriages, couplings, brakes, lighting, and so forth, to be submitted for their approval. A joint railway committee was accordingly formed of managers of the leading English railway companies and French railway engineers, with the result that the train as it stands now satisfies the requirements of the different authorities.

The arrangements of the train are as follows:—The first coach contains an office, with bed, fittings, desk, safe, &c., for the quartermaster-sergeant, partitioned off from a ward containing 30 beds. Coaches 2 and 3 have each

36 beds, with lavatory and lockers. Coach 4 has beds for 12 orderlies with two lockers and lavatory; a kitchen fully equipped and a 60 gallon hot-water tank, also store-room for linen. The first part of Coach 5 provides sleeping accommodation for the nurses, and nurses' and doctors' dining-rooms, also office and sleeping accommodation for the P.M.O. Then come the surgery and a sleeping room for doctors. Coaches 6 and 7 are similar to 2 and 3, and Coach 8 contains beds for 12 orderlies, a kit store, and a second kitchen. In accordance with the War Office desire, four other coaches, each for 50 sitting-up patients, have been added to the original eight, thus making with the engine and brake-van a train of 14 vehicles with a total length of about 700 feet. There is an ample supply of water throughout the train and gas and electric lighting, while in case of these failing Gimble candle lamps are placed in each carriage. The equipment of this train is ample and excellent, so that the train can, if necessary, be used as a stationary hospital on wheels.

THE FRENCH RED CROSS HOSPITAL AT ROYAUMONT.—Our own correspondent sends the following description of the military hospital at Royaumont:—"The Abbey of Royaumont dates from the thirteenth century, and has been occupied by religious communities from its foundation until some ten years ago. It is beautifully situated in the picturesque valley of the Oise in extensively wooded grounds. Its peacefulness renders it an ideal site for a military hospital. The abbey is built round three sides of a central court with cloisters, and two of these wings have been easily adapted to the needs of a modern hospital. On the ground floor are three medium-sized and two large wards, kitchen, lavatories, and bathroom. All have high-arched stone roofs; one, the ancient refectory, is oak-panelled, with windows facing south and west. New patients during their first days remark that on awaking from sleep they think they are in a church, so peaceful and so dignified are the arched roofs, stone walls and pillars, and the latticed glass of the tall windows. Two great staircases of oak lead to the first floor, where the ancient library of the monks, another stately hall, has been converted into a ward. Its windows look north and south; on one side the windows open on the terrace above the cloisters, where convalescents can lie in the sunshine. On the same floor in adjacent rooms are the X ray department, the dispensary, and the operating and sterilising rooms. On the same floor at a higher level are two long corridors with convenient bedrooms for the nurses and the medical and administrative staff; on the second floor are isolation chambers, storerooms, and bedrooms, and rooms for mending and sorting of clothes and arms. There is electric light throughout; hot water and anthracite stoves for heating have been inserted. Three motor ambulances fetch the wounded daily from the evacuation station at Creil. The first set of patients arrived about the middle of January; in March 161 entered; 106 were discharged. Shrapnel and bullet wounds form the majority of the cases which reach Royaumont, usually from 12 to 40 hours after being wounded. All wounds arrive with a clean, excellent first dressing, and the men have already received an injection of antitetanic serum. As a consequence, no cases of tetanus have been seen at Royaumont. The shrapnel wounds tend to become septic, and are treated at once with hydrogen peroxide and mercurial dressings. When examination by X rays reveals the presence of a foreign body it is localised by Hampson's method, and extraction is facilitated by the use of the telephone probe. Bullets embedded deeply in the muscles are rarely septic, and when left alone frequently give rise to so little trouble that their removal is unnecessary and inadvisable.

The military medical authorities have made a request to the chief surgeon at Royaumont that the number of beds be increased from the original 100 to 200—a request which is the more flattering, seeing that in January, when the hospital opened, it received no eager welcome and for some weeks had three-fourths of its beds unoccupied. Miss Ivens, M.B., M.S., is head surgeon; Miss Winifred Ross and Miss Ruth Nicholson act as assistant surgeons; Mrs. Berry and Miss Deborah Hancock as physicians; and the X ray and electro-therapeutic department is under the care of Dr. Agnes Savill. The hospital, whose official title is Hôpital Auxiliaire, No. 301, of Royaumont, Asnières sur Oise, is under that branch of the French Red Cross known as Secours aux Blessés Militaires."

CANADIAN BASE HOSPITALS.—The following is the staff for the base hospital contributed by the University of Toronto, which has been accepted by the War Office: Administrative staff: Lieutenant-Colonel James A. Roberts, F.R.C.S., commandant; Major William B. Hendry, second in command; and Captain M. J. L. Yellowlees. Surgical staff: Professor A. Primrose, Dr. F. N. G. Starr, Dr. Walter McKeown (of equal rank), Dr. E. S. Ryerson, Dr. Geo. E. Wilson, Dr. W. J. O. Malloch, Dr. R. Gaby, Dr. F. W. Watts, Dr. J. G. Gallie, Dr. H. Wookey, and in addition Dr. F. W. Marlow and Professor B. P. Watson. Medical staff: Dr. Andrew R. Gordon and Dr. Graham Chambers (of equal rank), Dr. D. McGillivray, Dr. Harold C. Parsons, Dr. D. King Smith, Dr. C. F. McVicar, Dr. Geo. F. Boyer, Dr. F. R. D. Hewitt, Dr. R. G. Armour, and Dr. J. H. McPhedran. Nose and throat: Dr. Gilbert Royce. Eye and ear: Dr. Wm. H. Lowrey. Genito-urinary: Dr. Robert Pearse. Sanitation: Professor John A. Amyot. Laboratory: Dr. Duncan Graham, Dr. N. C. Sharpe, Dr. A. A. Fletcher, and Dr. C. J. Imrie. Dental staff: Dr. George Dow. This staff has been selected from the various hospitals of Toronto; in addition some 80 nurses will also be selected.—The base hospital contributed by McGill University, which will be known as No. 3 McGill Hospital, and which also has been accepted by the War Office, will be under the command of the Dean of the Medical Department, Lieutenant-Colonel H. S. Birkett, with Lieutenant-Colonel H. B. Yates as second in command. The personnel was announced by our Canadian correspondent on March 20th.

THE FEEDING OF TROOPS IN THE FIELD.—Our Paris correspondent writes: Dr. Basset, inspector of provision factories in the 18th district, has pointed out that there is at present too exclusive an amount of flesh eating, for the French soldier refuses rice and makes but little use of bread. To remedy this state of things he suggests the preparation of four new forms of preserved foods, forming nutritious, hygienic, and agreeable dishes, the preparation of which is simple and practical. These dishes are a beef hash with vegetables, a *ragoût* of beef with vegetables, a *cassoulet* (a Languedoc dish of *haricots blancs* with pieces of goose, duck, mutton, or pork), and a mince of pork cooked in fat.

THE DEARTH OF MEDICAL OFFICERS.—A correspondent writes to us in reference to Sir Alfred Keogh's appeal, which appeared in THE LANCET of March 13th, to say that there are several reasons why medical men do not come forward. Among others he has heard the following: 1. Many now serving as combatants to fill up a niche, which they prefer, are willing to serve professionally from a sense of duty; naturally they will not accept a rank lower than their present one, and for this reason they are refused. 2. Medical men of many years' standing and in a good professional position very naturally object to be placed under men half their age and with no professional experience to speak of. 3. The offer of £8 8*s*. a week without any allowances is hardly attractive to a man, however patriotic he may be, who has to pay at least that amount per week to carry on his practice, in addition to the fact that his practice only earns about a quarter of what it should earn, and that his household and most of his professional expenses remain as before—the loss of most of his practice is hardly compensated for by a donation of £60 at the end of his service. A man who gives professional service is worth more than one who gives amateur service. The heads of the Royal Army Medical Corps do not know anything about private general practice, and cannot be expected to think of these things, but until they do it will be difficult to get men to come forward.

RE-EDUCATION OF CRIPPLED SOLDIERS.—The Colony for Cripples at Chailey, Sussex, has instituted military wards for convalescent soldiers where the men are taught various crafts in conformity with the disabilities imposed on them by their injuries. An appeal for special support was endorsed by the Bishop of London, who paid a surprise visit to the camp before going to the front for Easter. Things especially desired as gifts are a gramophone and records, a piano, bagatelle boards, a revolving shelter, books and magazines, and the loan of motor-cars. Communications may be addressed to Mrs. C. W. Kimmins, The Old Heritage, Chailey, Sussex.

HELP FOR THE HOSPITALS.—Lady Lawley, honorary secretary of the Queen Mary's Needlework Guild, has made a public announcement that with the approach of summer the necessity for woollen comforts no longer exists, nor for clothing for women and children; but owing to the duration of the war and the large number of casualties there is an increased demand for all necessaries and comforts for wounded and convalescent soldiers in the hospitals at home and abroad, for which several thousand more beds have to be equipped. Ladies are therefore requested to devote their energies to making for hospital use shirts, pyjamas, slippers, towels, bandages, nightshirts, dressing gowns, sheets, feather pillows, lint, together with socks, which are always useful.

CARDIFF MENTAL HOSPITAL.—The committee have agreed to hand over this hospital, situated at Whitchurch, to the War Office for use as a military hospital. The conditions, among other things, arrange that the Army Council is to make good expenditure or loss sustained. The War Office is to become responsible for the care and treatment, the hospital being handed over with its entire staff as a going concern. Any extra staff required will be appointed by the War Office. The scales of board and living for the staff are to be not less favourable to the staff than those at present obtaining. The medical superintendent will be the officer in charge under the direct control of the War Office. He will make contracts for supply and carry on the business side of the administration, opening a separate account and presenting his monthly accounts to the War Office through the Board of Control. The taking over of the hospital is to entail no expense whatever to the Cardiff ratepayers, and this includes the removal of patients to other mental hospitals and the charges made for their maintenance.

THE TRAINING OF WAR PROBATIONER NURSES.—The army appeal for nurses is meeting with a wide response. St. Bartholomew's Hospital, which has arranged a three months' course for war probationers, to fit them for service under fully qualified nurses in military hospitals, in accordance with the expressed desire of the Director-General of the Army Medical Service, as mentioned in our columns on April 3rd (p. 728), has received over 400 applications, of which not more than 40 could be accommodated. University College Hospital has also arranged for three and six months' courses for the same purpose.

READING AS A HOSPITAL CENTRE.—The War Office has taken over the Reading workhouse and several large elementary schools with the object of making Reading an important hospital centre. The transport service is to be organised entirely by the Berkshire Automobile Club, which will provide a staff of drivers.

DISINFECTANTS NEEDED FOR MONTENEGRO.—The prevalence of epidemics of typhus and typhoid fever in Montenegro has caused Sir Edward Grey to issue an appeal, through Sir J. Roper Parkington, for financial aid to supply the large quantities of disinfectants that will be required, the transit of which, it is believed, will be expedited by the Italian Government. Donations can be sent to the Duchess of Rutland, 16, Arlington-street, W., or to Lady Parkington, 58, Green-street, Park-lane, W.

THE Cross of Chevalier of the Order of Leopold has been conferred by the Belgian Government on Miss Beatrice Dormer Maunder, director of the Anglo-Belgian Hospital at Rouen, in recognition of her services since the outbreak of the war, first at Ostend and subsequently at Rouen.

THE Indian Field Ambulance working at Neuve Chapelle received the special commendation of Lieutenant-General Sir James Willcocks, commanding the Indian Army Corps in France.

BRISTOL ROYAL INFIRMARY.—At the annual meeting of the supporters of the Bristol Royal Infirmary on March 23rd Sir George White, the President, congratulated the governors on their prescience five years ago in placing the Royal Infirmary at the disposal of the nation to constitute the 2nd Southern Base Hospital for the sick and wounded in case of war. The report stated that at the end of 1914 no fewer than 1637 military patients had been admitted and a very large number of military out-patients treated, the committee having agreed with the War Office to undertake the feeding, cooking, provision of drugs and dressings, and laundry. In addition accommodation had also been found for many wives and families of soldiers coming from India and the colonies. Nevertheless, the treatment of civil patients had gone on as usual. Practically the whole of the honorary staff had been called up for military service, while of past and present sisters and nurses 103 were serving in military hospitals at home and abroad. Lieutenant-Colonel J. Paul Bush, C.M.G., R.A.M.C.(T.), expressed thanks on behalf of the War Office for the way in which the president and committee had responded to the calls made upon them.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the First Professional Examination of the Conjoint Board, held on March 23rd, 24th, 25th, and 26th, the following candidates were approved in the undermentioned subjects:—

Chemistry and Physics.—John Griffith Barrie, Guy's Hospital; Lionel Moore Billingham, Cardiff; Kevin Robert Chapple, St. Bartholomew's Hospital; Benjamin Young Harper Christmas, Middlesex Hospital; Cyril Bernard Dix, Guy's Hospital; Theodore Henry Dobrashian, University College; John Edwin Hardie Duckworth, Guy's Hospital; William Collins Faull, St. Mary's Hospital; Edgar Francis Job Jones, Cardiff; Francis William Kemp, Charing Cross and King's College; Elizabeth O'Flynn, London School of Medicine for Women; Arthur Gordon Ord, Guy's Hospital; Mohammed Abbas Ragy, King's College; Joseph Hajee Sullaiman, Guy's Hospital; and Henry William Miles Williams, Cardiff.

Chemistry.—Frederick Thomas Allen, St. Thomas's Hospital; William Edward Barnes, University College; Alfred Foster, St. Bartholomew's Hospital; Wahba Girgis, St. Mary's Hospital; Denis Paul Guilfoyle, St. Bartholomew's Hospital; Tudor David Llewelyn, Cardiff; Eva Morton, London School of Medicine for Women; and George Foster Smith, Manchester University.

Physics.—Ina Valentine Vincent, London School of Medicine for Women and Polytechnic Institute.

Biology.—Abraham Abelson, D.Sc. Lond., D. ès L., University College; Frank Barker, King's College; William Edward Barnes, University College; Willie Beaumont, London Hospital; Lionel Moore Billingham, Cardiff; Frederica Mary Bradley and Anna Bridget Broman, London School of Medicine for Women; John Francis Edward Burns, Bristol University; Norman Edward Davies Cartledge, St. Bartholomew's Hospital; Marjorie Carnsew Chappel, London School of Medicine for Women; Kevin Robert Chapple, St. Bartholomew's Hospital; Benjamin Young Harper Christmas, Middlesex Hospital; Percival Charles Collyns, St. Bartholomew's Hospital; Ivor Joseph Corbett and Ignatius Joseph Cruchley, London Hospital; Theodore Henry Dobrashian, University College; Arthur Duffy and Frank Edward Edwards, Manchester University; Gwilym Pennant Evans and William Collins Faull, St. Mary's Hospital; Schalem Finkelstein, Zürich and King's College; John Eskdale Fishburn, Portsmouth Technical College; Sydney Hazeldine, B.A. Cantab., University College; Arthur Robert Hill, Middlesex Hospital; Thomas James, St. Bartholomew's Hospital; Edgar Francis Job Jones, Cardiff; Francis William Kemp, Charing Cross and King's College; John Kendall and Gerald Baeyertz Kirkland, Guy's Hospital; Paul Lindsey, St. Bartholomew's Hospital; Tudor David Llewelyn, Cardiff; Eva Morton, London School of Medicine for Women; Arthur Richard Neckles and Arthur Gordon Ord, Guy's Hospital; Frederick Ferdinand Petersen, London Hospital; Eleanor Margaret Reece, London School of Medicine for Women; Charles Edward Roach-Smith and Geoffrey Bathe Withers, London Hospital; Peter Erbin Williams, B.Sc. Wales, Cardiff; and Sidney Wolff, Guy's Hospital.

At the Second Professional Examination of the Conjoint Board, held on March 25th, 26th, and 29th, 53 candidates presented themselves, of whom 29 were approved and 24 were rejected. The following are the names of the successful candidates:—

Hector Demetrius Apergis and Ernest Horace Bryant, Guy's Hospital; Charles Herbert Carroll and *Joseph Clinton Collins, London Hospital; Eric Croft, New Zealand and London Hospital; Mangalanathan Dominick, Madras University; Nassry Gobran El-Gawly, St. Bartholomew's Hospital; Mikhail Elias, St. Mary's Hospital; Frank James Harrington and George Raymond Hubbard, Guy's Hospital; John Powell Jones Jenkins, University College, Cardiff; Florence Maltby Kerruish, Liverpool University; Richard Turner McRae, London Hospital; Walter Harry Maudling, King's College; Elizabeth O'Flynn, Edinburgh and London School of Medicine for Women; May Olivera, L M S. Bombay, Bombay University; Ahmed Othman, King's College; Aron Pastel, Paris and King's College; Edward Rowley Peirce, Birmingham University; William Irving FitzGerald Powell, London Hospital; Ronal Eric Rampling, St. Thomas's Hospital; Florence Mildred Rhodes, London School of Medicine for Women; Khurshedjee Jamsedjee Rustomjee, Liverpool University; George Ernest Spero and Howard Branston Troup, London

Hospital; Robert Hugh Turner, Bristol University; Hugh Pennefather Warren, London Hospital; Francis Eaton Gordon Watson, St. Bartholomew's Hospital; and Henry George Watters, London Hospital.

* This candidate having obtained the highest number of marks in Anatomy will be recommended to the Council of the Royal College of Surgeons for the Begley studentship.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.—At the Preliminary Science Examination for the Licence in Dental Surgery, held on March 23rd, 25th, and 26th, the following candidates were approved in the undermentioned subjects:—

Chemistry and Physics.—Harold John Allen, Middlesex Hospital; Malcolm Beverley Burton, Norwich Technical Institute; Cyril Dudley Melville Dorward, Guy's Hospital; Kenneth Wilfred Eady, Brighton Municipal Technical College; Augustus Ford, West Ham Municipal Technical Institute; Ivan Jephson Gardiner and Dudley Keverne Gaskill, Guy's Hospital; Frank Hiam, Royal Dental Hospital; Charles Harold Sterne Horwitz, Guy's Hospital; Francis Joslin Janch, Royal Dental Hospital; Ernest Wilfrid Jarvis, Guy's Hospital; Charles George Lingford, Royal Dental Hospital; Isidore David Marks, Birmingham University; Kenneth Marshall, Walsall Municipal Institute; Edgar Evan Holt Phillips, Birkbeck College; Ernest Henry Richards, Guy's Hospital; and Norman Victor Wadsworth, Birkbeck College.

Chemistry.—Clifford Baker, Birmingham Municipal Technical School; Ronald Francis Binns, Polytechnic Institute; Frederick George Pritchard Flanders and Stanley Godsill, Guy's Hospital; Norman Leigh Simpson, Cardiff; and Sydney Stamp, Royal Albert Memorial College, Exeter.

Physics.—Iorwerth Dulyn Davies, Birmingham University; Leslie Frank Fouraker, Guy's Hospital; Florence Goodman, Polytechnic Institute; John James, University College, Southampton; and Herbert Newton Tiplady, Leeds Technical School.

UNIVERSITY OF LONDON.—At the Second Examination for medical degrees, for internal and external students, held recently, the following candidates were successful:—

Part I., Organic and Applied Chemistry.—Lena Cecilia Adam, London (Royal Free Hospital) School of Medicine for Women; Norman Dyer Ball, University College; Loveday Shackell Banes and Annie Hardy Banks, London (Royal Free Hospital) School of Medicine for Women; Monty Baranov and Henry Eric Beasley, University College; Levy Bernstein and Anthony Blackstock, King's College; John Douglas Magor Cardell, St. Thomas's Hospital; Wilfred Bayley Christopherson, St. Bartholomew's Hospital; Charles Eric Cobb, St. Thomas's Hospital; Humphrey Noel Felix Cook, University College; Anthony Beach Cowley, St. Bartholomew's Hospital; Joyce Emily Craggs and Nora Annie Crow, London (Royal Free Hospital) School of Medicine for Women; Evan Sherrah Davies, King's College; Idris Davies, University College, Cardiff; Mary Day, London (Royal Free Hospital) School of Medicine for Women; Francis Percival de Caux, St. Bartholomew's Hospital; Elizabeth Denniston, London (Royal Free Hospital) School of Medicine for Women; George Wilhelm Robert W. Dreiheller, St. Bartholomew's Hospital; Abraham Eidinow, London Hospital; Sylvia Victoria Elman, London (Royal Free Hospital) School of Medicine for Women; Frederick Augustus Evans, London Hospital; Donald Charles Fairbairn, St. Bartholomew's Hospital; Lilian Mabel Fisher, London (Royal Free Hospital) School of Medicine for Women; Gerald William Thomas Hunter Fleming, University of Durham; Abraham Foner, London Hospital; Wilfrid Frederick Francis, St. Mary's Hospital; Alfred Laurence Goff and Jacob Gorsky, King's College; *Walter Henry Grace, Guy's Hospital; Gwenvron Mary Griffiths, London (Royal Free Hospital) School of Medicine for Women; *Albert William Holgate, University College; Henry Nevill Hornibrook, St. Bartholomew's Hospital; John Francis Howells, University College; Marshall Jackson, St. Bartholomew's Hospital; Santo Weisberg Jeger, University College, Cardiff; Robert David Jones, University of Liverpool; Noel Edward Ffarnwell Kemm, University of Bristol; Vasant Ramji Khanolkar, University College; *Muriel Elsie Landau and Mary Kathleen Forsaith Lander, London (Royal Free Hospital) School of Medicine for Women; Charles Gordon Lewis, University of Birmingham; Simon Sally Liebermann and Ernest Kenneth Macdonald, St. Thomas's Hospital; *Janet McAllister McGill, London (Royal Free Hospital) School of Medicine for Women; Gerald Joseph Wyld McMichael, University of Birmingham; Vida Sara Maxwell, London (Royal Free Hospital) School of Medicine for Women; David Chaim Mintzman and Ludlow Murcott Moody, King's College; Edith Mary Ponsonby Morris, London (Royal Free Hospital) School of Medicine for Women; Edith Marjorie Newman, University College, Cardiff; John Ernest Nicole, King's College; Norah Dorothy O'Flyn, University College, Cardiff; Marguerite Henrietta Pam, London (Royal Free Hospital) School of Medicine for Women; Manek Jamshedji Panthaky, King's College; Rowland John Perkins, St. Bartholomew's Hospital; George Stuart Bain Philip, King's College and Charing Cross Hospital; Ruth Wade Plimsoll, London (Royal Free Hospital) School of Medicine for Women; Leonard Duncan Porteous, St. Bartholomew's Hospital; John Northley Julian Powlesland, Middlesex Hospital; Dorothy Priestley Priestley, Girton College and University of Leeds; Mary Millicent Prior, London (Royal Free Hospital) School of Medicine for Women; Ernest Frank Rabey, Middlesex Hospital; Ronald Seton Ralph, Guy's Hospital; Edward Douglas Thomas Roberts, St. Thomas's Hospital; Edward Snow Rose, St. Bartholomew's Hospital; Hugh Thornton Rymer, King's College; Solomon Nahum Senitzky, London Hospital; Bryan Buckley Sharp, St. Bartholomew's Hospital; Joseph Harold Sheldon, King's College; Arthur George Shurlock, Jesus College, Cambridge; William Henry Simmons, Guy's Hospital Bertram Leslie Slater, London Hospital; George John Sophianopoulos and Gilbert Patrick Staunton, St. Bartholomew's Hospital; Mary Sylvia Stocks, London (Royal Free Hospital) School of Medicine for Women; Harold Edward Suter, St. Mary's Hospital; Khiam Soon Tan, University College; Stanley Roy Tattersall, St. Thomas's Hospital; John Alan Tennyson-Smith, Dulwich College; Cyril James Thomas, St. Thomas's Hospital; Howard Metherell Toop, London Hospital; Robert Lawrence Walker, St. Mary's Hospital; Austin Darley Wall, St. Bartholomew's Hospital; Hygeia Leigh Josephine Wallace, London (Royal Free Hospital) School of Medicine for Women; Arthur Elston Ward, St. Thomas's Hospital; Robert Walter Warrick, Guy's Hospital and Finsbury Technical College; and Eugene Wolff, University College.

* Awarded a mark of distinction.

Part II.—Gustave Adler, London Hospital; George Eric Archer, Victoria University of Manchester; Eric Miles Atkinson, St. Bartholomew's Hospital; Roy Douglas Aylward, London Hospital; Kenneth Norman Grierson Bailey, St. Bartholomew's Hospital; James Reid Banks, University College; Claude Wells Woolloton Baxter and Eric Biddle, Guy's Hospital; Harold John Blampied, St. Thomas's Hospital; Israel Braun, St. Bartholomew's Hospital; Duncan Gillard Churcher and †Wilfrid Edward Le Gros Clark, St. Thomas's Hospital; Apollo John Cokkinis and Joseph Monlas Courtney, St. Mary's Hospital; Thomas Morley Cunnington, University College; George Vincent Davies, St. Mary's Hospital; Simon Cyril de Silva Wijeyeratne, University College; Howard Lexster Douglas, London Hospital; Monte Edwards, St. Thomas's Hospital; Grace Hamilton Ewart, London (Royal Free Hospital) School of Medicine for Women; William Feldman, University College; Douglas Hugh Aird Galbraith, Guy's Hospital; Maximilian Walter Geffen, University College; †Dorothy Gilford, London (Royal Free Hospital) School of Medicine for Women; Ernest Howard Glenny, St. Bartholomew's Hospital; ‡Henry Gluckman, London Hospital; Eryl Glynne, London (Royal Free Hospital) School of Medicine for Women; Alexander Fitzgerald Grattan Guinness, Guy's Hospital; Hubert Oliver Gunewardene, King's College; Joan Hardy, London (Royal Free Hospital) School of Medicine for Women; Thomas Lothian Heath, Guy's Hospital; Kenneth Reed Hill, University College; Bertha Hinde, London (Royal Free Hospital) School of Medicine for Women; Eric Clark Hinde and Valentine Robert Hirsch, Guy's Hospital; Theodora Johnston, London (Royal Free Hospital) School of Medicine for Women; John Isaïe Kühne, King's College and Charing Cross Hospital; Felix Raoul Leblanc, Guy's Hospital; Emily Catherine Lewis and Ethel Marion McCartney, London (Royal Free Hospital) School of Medicine for Women; Bruce Maclean, Puthiyaveettil Narayana Menon, and Martin Herbert, Oldershaw, University College; Alexander Edward Patrick Parker, King's College and Westminster Hospital; Irene Grace Parsons, London (Royal Free Hospital) School of Medicine for Women; Arthur Edmund Beer Paul, University College; Edwin Seymour Phillips, Guy's Hospital; Frank Portas, King's College and Westminster Hospital; Sybil Madeline Georgina Pratt, London (Royal Free Hospital) School of Medicine for Women; Henry Norman Pritchett, Guy's Hospital; Hywel Tegid Prys-Jones, University College, Cardiff; Mariamme Olive Ramsay, B.Sc., Joyce Baron Reed, Frances Elinor Rendel, Olive Rendel, and Gwendolen Mary Rolfe, London (Royal Free Hospital) School of Medicine for Women; James Paterson Ross, St. Bartholomew's Hospital; Henry Bret Russell, St. Thomas's Hospital; Eleanor May Scarborough, London (Royal Free Hospital) School of Medicine for Women; Simeon Cyril Shaw, Middlesex Hospital; Raghunath Dadoba Shirvalkar, University College; Arthur Anton Thiel, St. Bartholomew's Hospital; Benjamin Thomas, St. Mary's Hospital; Daniel Jenkin Thomas, B.Sc., and John Herbert Thomas, University College; George Edwin Tilsley, University of Bristol; Charles Maitland Titterton, St. Bartholomew's Hospital; Sydney Arthur Thomas Ware, St. Thomas's Hospital; Frederick William Arbuthnot Watt, London Hospital; Ralph Edwin Stuart Webb, Middlesex Hospital; Arthur William Wells, London Hospital; and John Prichard Williams, University College, Cardiff.

† Distinguished in Anatomy. ‡ Distinguished in Pharmacology.

N.B.—This list, published for the convenience of candidates, is issued subject to its approval by the Senate.

VICTORIA UNIVERSITY OF MANCHESTER.—At examinations held in March the following candidates were successful:—

FIRST M.B. AND CH.B. EXAMINATION.

Part I., Inorganic Chemistry and Physics.—Mary E. Boullen, G. H Buckley, T. H. S. Bullough, T. E. Coope, George Cumming, E. B. A. Edelston, F. C. Jones, Simon Kelly, James Leather, W. E. Mason, P. B. Mumford, E. R. Ormerod, Efimé Ratner, J. S. Robinson, Harry Stafford, Doris M. R. Tompkin, and Ruth A. Wilson.

Part II., Biology.—Nooman Abdoh, May Ashburner, Mary E. Boullen, G. H. Buckley, T. H. S. Bullough, T. E. Coope, George Cumming, Kathleen Doyle, Georgiana M. Duthie, E. B. A. Edelston, Olive M. Gimson, F. G. Hamnett, Archibald Harris, F. C. Jones, Simon Kelly, James Leather, J. A. Marriott, W. E. Mason, P. B. Mumford, J G. Nolan, E. R. Ormerod, William Reikan, J. S. Robinson, A. H. Sadek, Harry Stafford, Doris M. R. Tompkin, and Ruth A. Wilson.

Chemistry.--Elizabeth C. Davies and J. G. Nolan.

FIRST EXAMINATION FOR BACHELORSHIP IN DENTAL SURGERY.

Physics and Zoology.—E. L. Morgan.

DIPLOMA IN DENTISTRY (FIRST EXAMINATION).

C. C. Breakell, S. K. Gibson, J. C. Knowles, E. B. Manley, and Harold Walmsley.

Chemistry.—Bertram Wilkinson.

Physics.—D. M. Barnes, Norman Flitcroft, A. N. Place, and Matthew Raeside.

University of Glasgow.—The following candidates have passed the examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated—B., botany; Z., zoology; P., physics; C., chemistry:—

John Smith Aitken (Z.), Robert Caldwell Allan (Z.), Carl Otto Anderson, M.A. (B., P.), John Lang Anderson, M.A. (Z.), James Baird (Z., C.), Adam Barr (C.), Alexander Kidd Begg (Z , C.), Alexander Shanks Bisset (P.), Alexander Ronald Black (Z . C.), John William Stewart Blacklock (Z., C.), Donald Cameron Bowie (C.), Alexander Davie Boyd (Z.), Alexander Lothian Brough (Z., C.), Archibald Donald Brown (Z.), Murdoch Brown (Z., C.), James Caddies (Z., C.), Alister Campbell (Z., C.), Donald Stewart Campbell (B., Z.), James Gibson Campbell (Z., C.), Lovat Fraser Capell (Z., C.), John Parker Chisholm (P.), Booth Frederick Clarke (B., P.), Horace Collingbourne (B.), John Gilchrist Coltart (Z., C.), Alexander Conner Connell (Z., C.), George Michael Cooper (Z., C.), James Livingstone Cowan (Z., C.), Archibald Joseph Cronin (Z., C.), Edward Mitchell Erskine Cumming (B., P.), Douglas Roy Ferguson Davidson (Z.), John Campbell Dow (P.), John Grahame Drew (Z., C.), Peter Alexander Faichney (Z., C.), Robert Fletcher, M.A. (Z., C.), Colin Macphail Forbes (Z., C.), Robert Adam Forsyth (Z., C.), Allan Donald Fraser (C.), William Armour Galbraith (Z., C.), Matthew Forsyth Gibson (Z., C.), William Gibson (Z.. C.), Francis Denis Gillespie (Z., C.), Joseph Drysdale Glaister (Z., C.), Adam Smith Goudie, M.A. (P.), John Crawford Grant (Z., C.), John Forrest Hamilton (Z., C.), William Mason Hamilton (Z., C.), William Harrison (Z., C.), John Hewitt (Z., C.), Robert Gold Howat (Z.. C.), David Imrie (Z., C), John Edward Jeffrey (Z., C.), Andrew Yuill Pollok Johnston (Z., C.), Ian Gordon Kennedy (Z., C.), Robert Kennedy (Z., C.), William Milroy Kennedy (Z., C.), John Kirk, M.A., B.Sc. (Z., C.), Alexander Adam Kirkland (Z.), William Malcolm Knox (Z.), James Burnett Lawson (Z.), John Leishman, M.A. (Z., C.), Barnett Levine (Z , C.), Douglas Marshall Lindsay (Z)., David Logan (Z.,C.), George Alexander Lowe (Z., C.), Duncan MacColl (B., P.), Robert M'Courtney (Z.), Patrick Joseph M'Cusker (Z., P.), Andrew Buchanan Macdonald (C.), John MacColl MacDougall (Z., C.), Frederick M'Elwee (Z., C.), William Douglas Macfarlane (Z., C.), Robert M'Intosh M'Kean (B., Z., P.), William M'Kendrick (Z.), Kenneth Mackenzie (Z., C.), Alexander Henderson M'Lean (Z.), Angus Maclean (P.), Neil Alexander MacLean (Z., C.), William Henry M'Leish (Z., P.), Joseph Patrick M'Millan (Z., C.), Peter MacMurray (Z., C.), Alexander M'Callum Macqueen (Z., C.), Robert Mair (Z., C.), James Matheson (B.), John MacKean Maxton (Z., C.), Hugh Robertson Melville (B., P.), Modiri Silas Molema (Z , C.), James Bennie Morrison (C.), George Nelson (Z.), John Nicolson, M.A. (C.), John Stewart Nisbet (Z., C.), John Alexander Ramsay Oswald (Z., C.), Gilbert Paterson (Z., C.), James Paterson (Z.), William John Payne (Z., C.), John Pollock (Z., C.), Thomas Poole (C.), Rahmat Ullah Qureshi (Z., P.), Peter Crawford Rankin (Z., C.), David Reid (Z., C.), Andrew Morton Robertson (Z., C.). Henry Alexander Ross (Z., C.), Archibald Morton Sanders (Z., C.), John Kennedy Scotland (Z.), Thomas Sommerville (Z., C.), Donald M'Dougall Sproull (Z., C.), Horatio Walter James Steen (B., Z., C.), John Stevenson (B., P.), Robert Miller Stevenson (B., Z.), William Howie Stevenson (Z., C.), Andrew Sneddon Bennie Stewart (Z., C.), Noel Eustace Stone (Z., C.), Alexander Strang (Z., C.), Hugh Sutherland (Z., C.), William Crookenden Taylor (B.), William Robert Paton Templeton (Z.), Ernest John Tytler Thompson (Z.), John Todd (B., Z., C.), John Leonard Turpie (Z., C), John Walker Walker (Z., C.), William Burns Wallace (Z.), James Alexander Walls (B , Z.), Richard Jackson Watson (Z., C.), John Cunningham Watt (Z.,,) Robert Kennedy Watt (Z., C.), John Whitelaw, M.A. (Z. C.), Andrew Wilson (Z., C.), Robert MacLaren Wilson (B., P.), and Stephen Young (B., Z., P., C.)

Women.—Christine Calder Abernethy (Z., C.), Helen Frances Allinson (B., Z., C.), Ellen Davidson Anderson (Z., C.), Grace Hay-Anderson (Z , C.), Elizabeth Pace Cameron (Z., C·), Helen Clacher Cameron (Z., C.), Edith Chalmers (Z.), Mary Turner Liddell Clark (Z., C.), Emily Loudon Clow (Z., C.), Veronica Catherine Jessie Davies (Z., C.), Charlotte Ann Douglas (Z.), Helen Hogg (Z.), Marion Pitcairn Hogg (Z., C.), Elizabeth Smith Inglis (Z., C.), Margaret Logan (Z , C.), Alice M'Elwee (Z., C.), Alice M'Glashan (Z., C.), Evelyn Christina M'Donald M'Gregor (Z , C.), Ellen Thomson Mackenzie (Z., C.), Annie Isabel Christian Maclardy (Z.), Margaret Elizabeth M'Laren (Z., C.), Mabel Mary Maclean (Z., C.), Caroline Jane Maclennan (Z.), Muriel Mary M'Walter (Z.), Agnes Hislop Macwhirter (Z,), Florence Frances Mitchell Milne (P.), Georgina Murdoch (Z , C.), Kathleen Nicol (B.), Margaret Mitchell Paterson (Z.), Louisa Evelyn Pigeon (Z., C.), Margaret Innes Prangnell (P.), Eliza Dorothea Sandison (Z., C.). Elaine Bessie Stuart Stocquart (Z., C.), Muriel Amy Stowe (Z.), Jean Banks Thomson (Z.), Marion Thomson (B., Z., P., C.), Lilian Jane Taylor White (Z., C.), and Helen Barr Wilson (Z., C.).

The following have passed the examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated—A., anatomy; P., physiology; M., materia medica and therapeutics:—

John Alston (M.), Alexander Basil Austin (P.), Alexander George Brand (M.), William Moore Cameron, M.A. (A., P.), John Williamson Dalglish (M.), James Ferguson Duthie (M.), Kenneth Henry Dyke (A., P.), James Ewing (M.), Thomas Fleming (A.), Thomas Ronald Fulton (M.), Kenneth John Alexander Gillanders (A.), John Gray Gilmour (A.), William Hadden Gordon, M.A. (M.), Eduardo Guillermo Sanchez Hall (A., P.), Frederick William Hebblethwaite (A., P.), George Mundell Hetherington (M.), Arthur Robert Hill (M.), Tom John Honeyman (P., M.). James Neil Jamieson, M.A. (A., P.). Oswald Johnston (A., P.), Peter Stewart Kinloch (M.), William Fulton Kivlichan, M.A. (A.), Andrew Brown M'Aulay Lang, M.A. (A., P., M.), George Lean, B.Sc. (A., P.), James Liddell (A., P.), Frederick Richard Lubovius (A., P.), William Wilson Lundie (A., P.), Arthur Daniel Clark M'Gowan (P., M.), Alexander M'Cheyne Macintosh (A., P.), John Ebenezer MacIntyre (A., P.), Donald William Morison MacKenzie (A., P.). Neil Mackillop (M.), Robert Hugh M'Killop (A.), Donald Macqueen (A., P.), William M'William (A., P.), William Duff Miller (A., P.), George Anderson Mitchell (A., P.), James Moffat (P.), William Harold Palmer (M.), James Walker Patterson (A., P.), Samuel Murdoch Riddick (A., P.), Ian Menteith Robertson (A., P.), John Llewelyn Rowlands (P.), Alexander Benham Stich, B.Sc. (A., P.), Thomas Stewart Stirling (A., P.), James Joseph Treanor (A., P.), James Livingstone Walker (A.), Robert Nisbet Walker, M.A. (M.), John Allan White (A.), Kenneth John Talbot Wilson (M.), William Alexander Wilson (M.), and Robert Young (M.).

Women.—Janetta Margaret Alexander (M.), Annetta Gillies Turnbull Anderson (A., P.), Mabel Nellie Blake (A., P.), Margaret O'Rourke Gallagher (P.), Mary Brown Gillespie (A., P.), Margaret Hutchison Glen (M.), May Constance Boughton Leigh (A.), Margaret Jane Thorburn Leitch (M)., Elizabeth Clark M'Haffie, M.A. (A.), May Elizabeth MacIver (M.). Alice Julia Marshall (M.), Mercedes Margaret Morton (A.), May Isabella Turner Reid (M.), and Marion Watson (M.).

The following have passed the examination for the degrees of Bachelor of Medicine (M.B.) and Bachelor of Surgery (Ch.B.) in the subjects indicated—P., pathology; M., medical jurisprudence and public health:—

William Dick Allan (M.), John Alston (P.), William Baird (M.), James Beveridge (P., M.), James Prowse Broom (P.), Duncan Cameron (M.), Joseph Chalmers (M.), Douglas Hamilton Coats (P.), Alexander Findlay Cook (M.), Archibald Shankland Cook (M), James Crerar (P.), John Norman Cruickshank (M.), John Freeland Cunningham, M.A. (P.), John Williamson Dalglish (P.), Andrew Davidson (P., M.), George del Pino (P.), Michael Devers (P.), Alexander Dick (P.), John Dunbar (M.), James Ferguson Duthie (P.), James Ewing (P.), James Brown Fisher (P., M.), Matthew Mair Frew (M.), Leonard Woodburn Gemmell (P., M.), William Hamilton Gibson (P., M.), Norman William Gilchrist (P.), Thomas Gray (P.), David Heard (P.), Arthur Robert Hill (P.), Theodore Paton Hutchison (P.), James Scott Kinross (M.), George Kirkhope (M.), Robert Lindsay, M.A. (M.), Frederick Colquhoun Logan (P.), Donald John MacDougall (P., M.), James Wallace Macfarlane (M.), Gerald James M'Gorty (P.), Joseph Patrick M'Grechin (P., M.), John MacInnes (M.), Neil MacKillop (P.), Keith Stuart Macky (M.), Duncan M'Laren (P., M.), John Wilson Maclean (P.), Frederick Robertson Martin (P.), William Watson Morrison (P.), Alexander Morton (M.), John Hughes Murray (P.), William Harold Palmer (P.), James Alexander Paterson (P.), Thomas Smith Paterson (P.), William James Poole (P.), Thomas Joseph Desmond Quigley (P., M.), Alexander Wilkie Ritchie (M.), David Bell Robertson (M.), Thomas Robertson Sinclair (M.), William Mitchell Stewart (M.), John Lawrence Torley (M.), Robert Nisbet Walker, M.A. (P.), Robert Smellie Weir (P.), Clive Alan Whittingham (P., M.), and Kenneth John Talbot Wilson (P.).

Women.—Janetta Margaret Alexander (P.), Christina Blair Buchanan (M.), Maud Christine Cairney (M.), Ann Kelly Cormack (P.), Jane Beattie Davidson (M.), Jessie Crawford Gilchrist (M.), Florence Scott Kirk (P., M.), Margaret Jane Thorburn Leitch (P.), Elizabeth Stewart Martin (M.), Helen Young Murdoch, M.A. (M.), Mary Ishbel Sinclair (P.), Jane Stalker (M.), and Marion Baillie Darling Wilson (M.).

At the recent professional examinations for the degrees of M.B. and Ch.B. the following candidates passed with distinction in the subjects indicated:—

In (*a*) Zoology and (*b*) Chemistry—John E. Jeffrey. In Zoology—John W. S. Blacklock, Archibald D. Brown, John Hewitt, Robert G. Howat, Andrew S. B. Stewart, Ernest J. T. Thompson, Mary T. L. Clark, Charlotte A. Douglas, Margaret Logan, Evelyn C. M. M'Gregor, Caroline J. Maclennan, Georgina Murdoch, and Muriel A. Stowe. In Physics—Edward M. E. Cumming. In Chemistry—Gilbert Paterson, William J. Payne, and John Pollock. In Physiology—Alexander B. Stitch. In Materia Medica and Therapeutics—Margaret H. Glen. In Pathology—Frederick C. Logan and Clive A. Whittingham. In Medicine—William E. Boyd. In Surgery—Alfred T. Logan. In Midwifery—Hugh B. Lawrie.

University of Aberdeen.—At the graduation ceremony on March 30th the following degrees, among others, were conferred:—

Doctor of Medicine.—Sebastian Valentyn Van Niekerk, Edward Wood Wood-Mason (old regulations), Thomas Charles McCombie Young, and Robert Semple.

Bachelor of Medicine and Bachelor of Surgery.—William Anderson, Elizabeth Grace Berneaud, Douglas Wales Berry, Ronald John Bruce, Patrick Thomas Catto, Austin Basil Clarke, Reginald Tom Cox, Douglas Cran, Alfred George Brown Duncan (second-class honours), George William Elder, Alexander Farquhar, Robert Forgan, John Alexander Innes, John William Innes, William Hunter Kay, William Leslie, Herbert John Adam Longmore, John Moir MacKenzie, John Moir, Robert Munro, Robert Boulton Myles, Eric Newton, Cameron Macdonald Nicol, Forster Heddle Brown Norrie, Gilbert Wolridge Rose, Colin George Shearer, and William Joseph Webster.

Diploma in Public Health.—John McGregor Hartley Reid and Benjamin Theodore Saunders.

The Chelsea Hospital for Women has received from the trustees of the Zunz bequest £500 for the maintenance of the Annie Zunz Ward.

A Centenarian.—Mr. William Perkins, of Shepau Stow, Lincolnshire, has just celebrated his 103rd birthday.

Royal Free Hospital, Gray's Inn-road, W.C.—Senior Resident Medical Officer. Salary £200 per annum, with board, residence, and washing. Also Assistant Anæsthetist (part-time). Salary £50. Also Female Junior Obstetric Assistant. Board, lodging, and washing provided.

Royal Institute of Public Health, 37, Russell-square, W.C.—Demonstrator in Bacteriology.

Royal Waterloo Hospital for Children and Women, S.E.—Senior and Junior Resident Medical Officers. Salary at rate of £150 and £100 per annum respectively, with board and washing.

St. Mary's Hospital for Women and Children, Plaistow, E.—Junior Resident Medical Officer for three months. Salary at rate of £90 per annum, with board, residence, and laundry.

Salisbury General Infirmary.—House Surgeon and Assistant House Surgeon, unmarried. Salary £100 and £75 per annum, respectively, with apartments, board, lodging, and washing.

Salford Royal Hospital.—Junior House Surgeon and Casualty House Surgeon for six months. Salary at rate of £100 per annum each, with board and residence.

Salvation Army Mother's Hospital, Clapton, N.E.—Female Resident Medical Officer.

Sheffield, Ecclesall Bierlow Union.—Resident Assistant Medical Officer. Salary £250 per annum, with board, washing, and apartments.

Sheffield Royal Hospital.—Assistant House Surgeon and Assistant House Physician.

Sheffield Royal Infirmary.—House Surgeon and Assistant House Physician. Salary £100 per annum, with board and residence.

Shrewsbury, Royal Salop Infirmary.—House Physician. Salary at rate of £110 per annum, with board and apartments.

South Shields, Ingham Infirmary and South Shields and Westoe Dispensary.—Senior House Surgeon. Salary £150 per annum, with residence, board, and washing.

Stafford County Mental Hospital.—Female Temporary Assistant Medical Officer. Salary £250 per annum, with board, apartments, and laundry.

Stoke-on-Trent County Borough.—Female Medical Officer. Salary £300 per annum.

Stoke-on-Trent, North Staffordshire Infirmary, Hartshill.—House Physician and House Surgeon, unmarried. Salary at rate of £150 per annum, with board, residence, and washing.

Swindon Borough Education Department.—School Medical Officer. Salary £300 per annum.

Taunton and Somerset Hospital, Taunton.—Senior House Surgeon. Salary £120 per annum, with board, lodging, and laundry.

Ventnor, Isle of Wight, Royal National Hospital for Consumption and Diseases of the Chest on the Separate Principle.—Assistant Resident Medical Officer, unmarried. Salary £150 per annum, with board, lodging, &c.

Wakefield, Clayton Hospital.—Female Junior House Surgeon. Salary £120 per annum, all found.

Wandsworth Union Infirmary, St. John's-hill, Clapham Junction, S.W.—Assistant Medical Officer, unmarried, for six months. Salary at rate of £5 5s. weekly, with board, lodging, and washing.

Warrington Infirmary and Dispensary.—Junior House Surgeon. Salary at rate of £120 per annum, with board, apartments, and laundry.

West End Hospital for Diseases of the Nervous System, Paralysis, and Epilepsy, 73, Welbeck-street, W.—Clinical Assistants to Out-patients' Physicians.

West Ham and Eastern General Hospital, Stratford, E.—House Physicians. Salary £120 and £100 per annum, with board, residence, and washing.

Whitehaven and West Cumberland Infirmary.—House Surgeon. Salary £150 per annum, with board, lodging, and attendance.

The Chief Inspector of Factories, Home Office, London, S.W., gives notice of vacancies for Certifying Surgeons under the Factory and Workshop Acts at Irlam and at Liverpool, Garston, in the county of Lancaster.

The Home Secretary gives notice of three vacancies for Medical Referees under the Workmen's Compensation Act, 1906, for the Sheriffdom of Ayr. Application should be addressed to the Private Secretary, Scottish Office.

Births, Marriages, and Deaths.

BIRTHS.

Donald.—On March 30th, at Dean-street, Liskeard, Cornwall, the wife of John Donald, M.D., of a son.

Griffith.—On March 30th, at Cavendish-road, St. John's Wood, to Helena (née Fletcher) and Harold Kinder Griffith, F.R.C.S., R.A.M.C.(T.), a son.

MARRIAGES.

Forrester—Aylward.—On April 8th, at St. Mary's, Northiam, Sussex, by the Rector, the Rev. A. Frewen Aylward, father of the bride, Archibald Thomas William Forrester, M.D. Lond., to Margaret Mary Frewen Aylward, daughter of the Rev. A. Frewen and Mrs. Aylward, Northiam Rectory, Sussex.

Jones—Graham.—On April 8th, at St. Mary Abbots, Kensington, London, Hugh Richard Jones, M.D., Abercromby-square, Liverpool, to Margaret, second daughter of the late George Graham, Lockerbie, Dumfriesshire.

DEATHS.

Dalby.—On Good Friday, April 2nd, at 14, Royal-terrace, Weymouth, Augustus William Dalby, L.R.C.S., L.R.C.P. Edin., aged 55, of Argyll House, Frome, Somerset, second son of the late William Bennett Dalby, M.D., R.N., of Torquay. Funeral service at Frome Parish Church on Tuesday at 2.30.

Hannah.—On April 6th, at Rock House, Ashton-in-Makerfield, Lancs., from pneumonia, Nathan Hannah, L.R.C.P. Edin., L.F.P.S. Glasg., Medical Officer of Health, Ashton-in-Makerfield Urban District.

Lentaigne.—On March 30th, at Merrion-square, Dublin, Sir John Lentaigne, F.R.C.S. Irel., aged 59 years.

Lewis Jones.—On April 4th, at Harley-street, W., Henry Lewis Jones, M.D., F.R.C.P., aged 58 years.

Wilson.—On April 1st, at The Laburnums, Standish, near Wigan, Joseph Harwood Wilson, M.D., aged 49 years.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

VITAL STATISTICS OF NYASALAND.

A report, prepared by Mr. A. M. D. Turnbull, assistant chief secretary, on the Blue-book of the Nyasaland Protectorate for the year 1913–14, states that there has been an increase in the European population, which on March 31st, 1914, was returned at 799. The Asiatic population on the same date was 408, whilst the native population is estimated at 1,065,119. Twenty-six European births and seven deaths were registered during the year, the birth-rate being 32·54 and the death-rate 8·76 per 1000. There were no Asiatic births, although seven had been recorded in the previous year; the deaths among Asiatics decreased from 8 in 1912–13 to 1 in 1913–14. Nine European marriages were celebrated during the year. Native Christian marriages celebrated under the Christian Native Marriage Ordinance numbered 254. No organisation exists at present for the registration of marriage by native custom or for recording births and deaths among the native population. The health of the Protectorate generally was satisfactory during the year and there was no outbreak of epidemic or other sickness as a factor in the death-rate.

The investigation of ankylostome infection amongst natives was continued in various districts, and the results show that this disease prevails with about equal intensity throughout Nyasaland. In regard to sleeping sickness it may be said that up to the present there would appear to be no tendency to any spread of the disease. Sixty-four cases were reported during the year. The preventive measures which have been adopted consist mainly of clearings around villages and along some of the more frequented paths in the infected areas. Where extensive clearings have been made a quite appreciable diminution in the number of tsetse flies has been noticed. Only one case of small-pox was recorded, the patient having acquired the infection in the adjoining Portuguese territory. Measures were at once instituted to prevent any spread of infection, and proved completely successful. There has been no recurrence of small-pox in epidemic form since the year 1909, a result which is due to the systematic vaccination of the general population and which has removed one of the principal factors militating against a normal increase of population. The total number of vaccinations performed during the year was 143,052.

Excluding injuries and the commoner skin affections, the chief causes of sickness in order of frequency were digestive and bowel complaints, bronchitis, malaria, dysentery, and syphilis. Among the diseases with increased admission rates were malaria, respiratory disorders, venereal diseases, and tuberculosis. Chicken-pox and measles showed a considerable decrease. Malarial fever represented nearly 5·64 per cent. of the total admissions, and was most prevalent in January, February, and May, or, in other words, at the height of, and shortly after, the rainy season. The health of European officials has been satisfactory on the whole, and there have been no invalidings. There were two cases of enteric, one of which terminated fatally. The general adoption of quinine prophylaxis caused an appreciable decline in the admissions for malarial fever. In regard to the general European population, a large proportion of the sick are treated by mission doctors, and therefore do not come under the notice of the medical officers. Five deaths were recorded by the medical staff—viz., one each from malarial hyperpyrexia, cerebral embolism, myocarditis, appendicitis, and septicæmia. The number of European patients admitted into the Government hospitals amounted to 73.

The climate of Nyasaland falls into two main divisions: (1) that of the Shiré River Valley and Lake Nyasa; and (2) the other of the remaining districts of the Protectorate, which lie at a much higher elevation. There are consequently considerable variations in temperature and humidity, the low levels being hotter and drier than the highlands. The seasons comprise a rainy season, extending, as a rule, from the end of November to the end of March, and a dry season during the remaining portion of the year. During the past five years, however, there has been a tendency for the rains to commence later. The rainfall at Zomba observatory for the calendar year 1913 was 51·73 in., whilst at Mlanje station (2462 ft. above sea-level) it was 87·70 in. The mean temperature of the air at the observatory was 68° F., the highest temperature recorded being 92° on Oct. 15th, and the lowest 47° on June 14th.

"THE ELECTRIC TELEGRAPH ORIGINALLY PROPOSED BY A FRENCH MEDICAL PRACTITIONER."

IN view of the amount of telegraphy being done in all directions in the present war it may be interesting to recall the claim of a French medical man to be the pioneer. The first idea of telegraphing by means of an electric current, it appears, belongs to M. Henry, surgeon at Arnaville (Meurthe), who had so far back as 1836 established a correspondence by wires with M. Lapostolle, a well-known natural philosopher. The wires were made to run from the villa of the former to that of the latter gentleman: one shock signified A; two, B; three, C, &c. M. Henry wrote, on Oct. 31st, 1836, to the Minister of Commerce of Public Works, touching his telegraph, and received an answer stating that the invention had been submitted to the Board of Arts and Manufactures, who was of the opinion that the plan could not be applied on a large scale, and would not answer the expectations of the author. The latter was discouraged at this reply, and discontinued his experiments. Claims have been made on behalf of a Mr. Ronalds, of Hammersmith, who experimented from 1816 to 1823, but apparently only on his lawn.

"WOMEN POLICE."

IN reference to a note with the above heading which appeared in THE LANCET of March 27th, p. 686, Mrs. A. Gilbertson writes to us to point out that the women "patrols" who are employed by the National Union of Women Workers at Hove alone are officially authorised, and they do not pose as policewomen or wear a uniform, but are just what they claim to be, "patrols" only, wearing simply a badge.

SMALL-POX IN THE PHILIPPINE ISLANDS.

IN the second quarterly report for 1914 of the Bureau of Health for the Philippine Islands, Surgeon Victor G. Heiser says there has been practically no small-pox in the Philippine Islands for the period covered by the report save in provinces where regular vaccinations have not been carried out. In Samar and Leyte several hundred cases occurred, but these were confined almost entirely to unvaccinated individuals. This experience, it is pointed out, shows the great importance of prompt vaccination of all new-born children and other unvaccinated individuals who may come into the community of a province after it is once freed of small-pox. As an example, it is mentioned that in the city of Manila, where vaccination is thoroughly carried out, there has not been a death from small-pox since June, 1909.

THE MEDICAL PICKWICK.

To the Editor of THE LANCET.

SIR,—Your interesting note in THE LANCET of March 27th (p. 686) on this subject draws attention to the fact that Mr. Pickwick's "stormy interview with Dr. Payne and Dr. Slammer at the Bull at Rochester and his adventures with Bob Sawyer and Benjamin Allen are his closest relations with our profession." I am, however, inclined to think that Dickens was a reader of medical papers dealing with the anomalies and curiosities of medicine. Referring to one of the few pathetic scenes in the "Pickwick Papers" (published in 1836–37), the meeting of Mr. Pickwick with Mr. Alfred Jingle in the Fleet Prison, we read that after Mr. Alfred Jingle had told of how he had "lived on a pair of boots—whole fortnight, silk umbrella—ivory handle—week." "Oh," said Mr. Pickwick, "I understand you. You have pawned your wardrobe." This very closely follows the description George Alexander Stevens, author of "Satirical Songs" and a lecture on "Heads," gives of his life in the Fleet Prison in his famous letter to Dr. Miller, of Doncaster, published in Wadd's monograph on "Corpulency." Stevens, after stating that he had swallowed his whole wardrobe, goes on to say, "he was about to eat his last waistcoat," and continues: "Themistocles had many towns to furnish his table, and a whole city bore the charge of his meals. In some respects I am like him, for I am furnished by the labours of a multitude. A wig has fed me two days; the trimming of a waistcoat as long. A pair of velvet breeches paid my washerwoman; and a ruffled shirt has found me in shaving. My coats I swallowed by degrees; the sleeves I breakfasted on for weeks; the body, skirt, &c., served me for dinner two months. My silk stockings have paid my lodgings; and two pair of new pumps enabled me to soke several pipes. It is incredible how my appetite (barometer like) rises, in proportion as my necessities make their terrible advances. I here could say something droll about a good stomach; but it is ill jesting with edged tools, and I am sure that is the sharpest thing about me. You may think I can have no sense of my condition, that, while I am thus wretched, I should offer at ridicule: but people constituted like me, with a disproportioned levity of spirits, are always most merry when they are most miserable; and quicken like the eyes of the consumptive, which are always brightest the nearer the patient approaches dissolution. However, to show you I am not lost to all reflection, I think myself poor enough to want a favour and humble enough to ask it here. I might make an enconium on your good nature, humanity, &c.; but I shall not pay so bad a compliment to your understanding as to endeavour by a parade of phrases to win it over to my interests. If you could any night, at a concert, make a small collection for me it might be a means of my obtaining my liberty; and you well know the first people of rank abroad will perform the most friendly offices for the sick; be not, therefore, offended at the request of a poor (though deservedly punished) debtor."

Wadd's work was published by Ebers, of Old Bond-street, in 1829, and had a large circulation, being written in a popular style and containing many humorous anecdotes in its "Mems on Diet and Dietetics." It is, however, quite possible that Dickens never saw George Alexander Stevens's letter; but if so, it is an extraordinary coincidence that Jingle, when on his last legs, should give expression to Stevens's thoughts and proclaim them in the same prison.

I am, Sir, yours faithfully,
Dublin, March 29th, 1915. GEORGE FOY.

BEEF INSPECTION.

THE *Annali di Medicina Navale e Coloniale* has published a supplement on beef inspection, by Surgeon-Captain Dr. N. Ercole, of the Italian navy. The author takes a wide view of his subject, dealing with the inspection of live cattle, of carcasses, and of preserved meats. He discusses the tricks of the trade apt to mislead an examiner, and his statements concerning the daily length of march possible to a fat steer, and the loss of weight of overdriven cattle will be very informing to naval officers concerned with such questions. As to tubercle, any portion of a carcass is condemned whose lymphatic glands, even one of them, is tuberculous, and that portion is denatured and destroyed; if, however, the lesion is single and of small extent, the rest of the carcass is allowed to be sold, but must first be boiled for at least an hour. The author notes that the ilio-lumbar glands, if tuberculous, and only then, give off sulphuretted hydrogen when treated with sulphuric acid.

ST. LUCIA.

ACCORDING to the Blue-book for 1913–14 of this, the largest of the group of the Windward Islands, the population is estimated at 50,809—23,367 males and 27,442 females. The birth-rate (excluding stillbirths) was 34·5 per 1000 of the population, and the death-rate 17·4 per 1000. There was one death from snake-bite. The Victoria Hospital at Castries is the one general hospital for the colony. It is a fine stone building, well situated, and has been considerably improved of recent years. A trained nurse-matron from England assumed her duties in 1914. The daily average number of patients was 63. Small buildings are provided in the out districts at Soufrière, Dennery, and Vieux Fort, which are used as casualty hospitals for accident and emergency cases. In the Yaws Hospital there was a daily average of 22 patients. The voluntary influx of patients for treatment with the drug salvarsan continued unabated during the year, and 147 cases were treated; the number would have been much greater but for a shortage in the supply of the drug. The medical officer in charge, Dr. A. F. Hughes, reports that up to the time of his report he had treated 413 cases, and that out of this number there had been only 21 cases of recurrence of the disease. In the latter connexion the medical officer refers to the difficulty of distinguishing between *bonâ-fide* recurrences and cases of reinfection.

The average annual rainfall for the island, recorded at 25 stations, was 83·75 in.; the highest was 106·65 in., at Warwick Estate in the Choiseul district, and the lowest, 48·50 in., at Beausejor Estate in the Vieux Fort district. The mean monthly temperature recorded in the shade at the Botanic Station in Castries was 78·2° F. The maximum shade temperature of 89·5° was recorded on May 19th and Sept. 4th and the minimum of 62·0° on Feb. 19th.

COLLOSOL ARGENTUM IN CEREBRO-SPINAL MENINGITIS.

Messrs. Oppenheimer, Son, and Co., of Queen Victoria-street, London, E.C., state that collosol silver as prepared in the Crookes laboratories has been recommended as a prophylactic against attacks of cerebro-spinal meningitis. The series of collosols are destructive to all kinds of pathogenic bacteria, even when used in minute quantity. A special nebuliser (the Optimus) is made for using collosols as an inhalation or spray. It is constructed entirely of glass.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

THURSDAY.

SECTION OF DERMATOLOGY (Hon. Secretaries—S. E. Dore, A. M. H. Gray): at 5 P.M.

Demonstration of Cases (at 4.30 P.M.).

FRIDAY.

SECTION OF ELECTRO-THERAPEUTICS (Hon. Secretaries—S. Gilbert Scott, E. P. Cumberbatch): at 8.30 P.M.

Report of the Sub-committee on the Standardisation of the Opaque Meal, presented by Dr. R. Morton.

Discussion:

On the Opaque Meal Method of Examination.

The following will take part in the discussion:—Dr. Hertz, Dr. R. Morton, Dr. A. E. Barclay, Mr. Gilbert Scott.

Those wishing to join in the discussion please notify the Hon. Secretary as soon as possible.

HUNTERIAN SOCIETY, Barbers' Hall, Monkwell-street, E.C.

WEDNESDAY.—9 P.M., Papers:—Captain F. R. Humphreys, R.A.M.C.(T.): The Work of a Field Ambulance.—Dr E. Maynard: Experiences of a Temporary Naval Surgeon on H.M.S. *Carmania*.

SOUTH-WEST LONDON MEDICAL SOCIETY, Bolingbroke Hospital, Wandsworth Common, S.W.

WEDNESDAY—9 P.M, Mr. F. J. Steward: Colitis from the Surgical Standpoint.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF PHYSICIANS OF LONDON, Pall Mall East.

TUESDAY AND THURSDAY.—5 P.M., Oliver-Sharpey Lectures:—Mr. J. Barcroft: A Comparison between Some Physiological and Pathological Conditions.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Museum Demonstrations for Advanced Students and Medical Practitioners:—

MONDAY.—Mr. Shattock: Specimens of Syphilis.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

WOUND INFECTIONS

AND ON

SOME NEW METHODS FOR THE STUDY OF THE VARIOUS FACTORS WHICH COME INTO CONSIDERATION IN THEIR TREATMENT.

Delivered before the Royal Society of Medicine on March 30th,

By COLONEL SIR A. E. WRIGHT, M.D., F.R.S.,

A CONSULTING PHYSICIAN TO THE EXPEDITIONARY FORCE.

(From the Research Laboratory attached to No. 13 General Hospital, Boulogne-sur-Mer.)

(Continued from p. 741.)

What are the Factors which Influence the Emigration of White Blood Corpuscles into the Wound?

I PASS now to consider yet another subject-matter—the emigration of leucocytes into the wound. I need not labour the point that this is a factor which may determine the issue of an infection; nor need I point out that it behoves us to acquire a control over the movement of leucocytes, and then to turn this to account, as the case may be, by activating or restraining emigration.

Broad foundations for our work have, as you know, already been laid by the brilliant researches of Metchnikoff. But it was with Metchnikoff always a question of experiments *in vivo*—that is, of experiments carried out under conditions which cannot be sufficiently simplified to give quite unambiguous answers. And we require for the elucidation of our problems and for all detail work connected therewith, absolutely simple crucial experiments, such as can only be made *in vitro*.

The line of thought which I have followed in elaborating a laboratory method for the study of the phenomena of emigration is the following:—The leucocytes in extravascular blood are known to retain their emigrating power. A difficulty will, however, when we are working with extravascular blood, attach to our observations by reason of the fact that we have not at disposal such a containing membrane as the capillary wall. We are, in fact, in dealing with extravascular blood confronted with a situation similar to that which would be encountered in observations *in vivo* if the capillary walls were to give way, and we had to make observations on emigration in a portion of tissue which was flooded out by red corpuscles.

I had hoped at first to be able to circumvent this difficulty by taking advantage of the fact that when clotting occurs the red blood corpuscles become enclosed in a meshwork of fibrin, after the manner of fish in a net. But all my efforts to make the fibrin meshwork take over the office of a containing membrane were defeated. No matter how tenderly the clot was treated the meshes of the net broke, and hæmorrhage from the clot interfered with the observations.

A second difficulty also presented itself. When in the living body white corpuscles emigrate into connective tissue it is possible to register their travel because they move forward through a retaining meshwork. It would not be possible to do so if they merely passed out into fluid, to be afterwards carried hither and thither by every chance convection current. Exactly the same applies to the extravascular blood. The emigrating leucocyte must be provided with some sort of scantling to move forward upon, and come to rest in.

After a time I alighted on a method which satisfies the two aforementioned experimental requirements, and which, as I think, provides all that is required for a quantitative estimation of emigration. Let me first tell you the general lines upon which the method proceeds, and then set out the details of the technique.

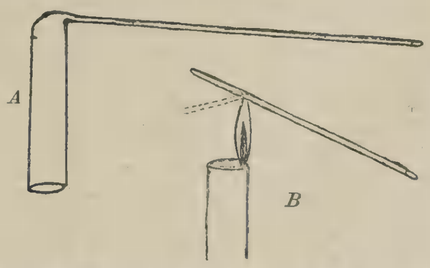
Principle of the Method Employed for making Observations on Emigration.

The principle of the method is as follows:—We fill in a capillary tube with blood from a prick in the finger, immediately place the capillary tube in the centrifuge, and centrifugalise until we have carried down all the corpuscles. We have now in the upper half of the tube a plasma which has been completely freed from all formed elements; and in the lower half of the tube, at the bottom, the red blood corpuscles intermixed with a certain number of polynuclear white blood corpuscles; and above this a layer made up predominantly of white blood corpuscles—these last in the front ranks consisting almost exclusively of small and large mononuclears. The blood now clots. And this gives in the upper half of the tube a clot consisting of fibrin without any formed elements—let us call this the *white clot*—and in the lower half of the tube a clot—let us call this the *red clot*—which holds all the corpuscles in its meshes. When a chemotactic stimulus now comes into application from above the white blood corpuscles will come out from the red clot and will travel upwards through the meshes of the white clot—afterwards maintaining their positions so as to allow of our making measurements and enumerations. We will now pass to the details of the technique.

Details relating to Apparatus and Procedure.

With regard to apparatus, all that is required is a supply of flat capillary tubes. By using flattened capillary tubes we obtain a thin clot, which can more easily be examined under the microscope.

Fig. 5.



Method of making emigration tubes. A, Method of giving the flattened conformation to the capillary stem. B, Method of binding the tube round to form an elbow.

We make these tubes—and they may conveniently be called emigration or chemotactic tubes—either out of a small test-tube, or out of a length of fairly wide-bored glass tubing. We heat in the blowpipe flame until the glass becomes very plastic; then, making a sharp outward turn with the right wrist, bend the tube round through a right angle, giving it the proper flattened conformation; and then draw out into a long flat capillary stem. (Fig. 5, A). We then cut this through at the point where it begins to lose its flattened conformation; and so leave attached to the next segment a sufficient length of tube to take hold of when we go to work upon

No. 4781.

it. When a sufficient number of lengths of flattened stem have been provided, we cut these up into segments of about 8 cm. in length; arrange them side by side after the manner of a palisade; and then with our glass writing pencil rule two lines across the face of our tubes. The first of these lines ought to fall somewhere in the middle. It is to serve as a fiducial mark for filling in the blood from the finger. The second line, which may conveniently fall at a point to about half or three-quarters of a centimetre to the end of the tube, is to serve as a fiducial mark in filling in the chemical agent whose effect we are to study.

The tube may now be used just as it is: or we may before using it furnish it with a syphon-curve by bending it round at the level of our second fiducial mark. We do this by taking up each tube separately, holding it horizontally, and then passing it rapidly to and fro through a small by-pass flame. The action of gravity will then, as soon as the glass softens, bend round the tube for us. (Fig. 5, B.)

Method of Using the Emigration Tubes and Bringing the Chemotactic Agent into Application.

The emigration tube is first filled in up to the midway point with blood drawn from a puncture in the finger. In the case where we employ a bent tube this is done by letting the blood flow in through the syphon curve.

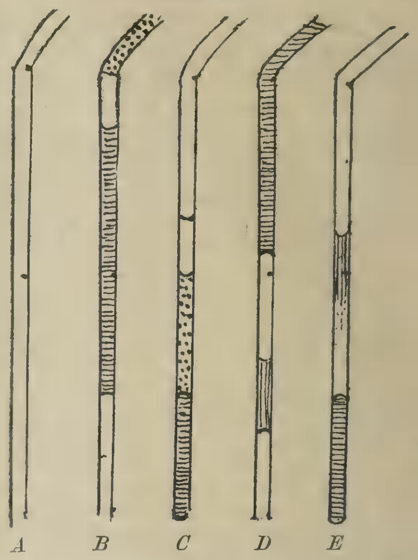
The chemotactic agent can now be brought into application in three different ways.

1. *It may simply be superimposed upon the clotted blood.* This is done by using a *filiform pipette*, made by heating the stem of an ordinary capillary pipette in a small by-pass flame and drawing out, while we with a rubber teat apply internal pressure to prevent the walls of the hair-fine tube collapsing. Considered as a method for bringing a chemotactic agent into immediate application, this method falls short in the respect that the chemical has to diffuse down through the whole white clot before it comes into operation. In view of this, the method does not lend itself to the institution of any comparisons between normal blood and anæmic blood. For the experimental conditions are not comparable when our chemotactic agent has, in the one case, to diffuse through a length corresponding to half the column of blood; and, in the other case, through a length which may amount to nine-tenths of that column.

2. The *second* method of bringing the chemotactic agent into application is that of *superimposing the chemotactic agent upon the unclotted blood.* (Fig. 6, B and C.) Having filled in a curved emigration tube up to mid-point mark with blood; we tilt the tube so as to take in a dividing bubble of air; then fill it up as far as the elbow with the chemotactic agent; and then, after sealing up the distal end of the tube, proceed to centrifuge. This method is applicable, in particular, when we are working with bacterial suspensions; for while the watery suspending fluid remains, by reason of its light specific gravity, on the top, the microbes are, by virtue of their higher specific gravity, carried down into the plasma, to be embedded in the white clot all the way down to the leucocytic layer.

3. The *third* method is the method of *traversing.* (Fig. 6, D and E.) In employing this we may use either a straight or a bent emigration tube. We fill in, first, with our column of blood; then follow on with the dividing bubble of air; and then, making use of the forerunning column of blood to serve as a brake, fill in up to the fiducial point with the chemotactic agent.[1] Finally, we seal up that end of the tube which has served as an inlet and place the tube in the centrifuge.

FIG. 6.



Method of adding chemotactic fluid to blood. A, Curved emigration tube, empty. B, Tube filled in with a column of blood, a dividing air bubble, and then, as far as the elbow, with a bacterial suspension. C, Tube after centrifugalisation. The bottom of the tube is occupied by the "red clot," and the intermediate portion by the "white clot" and implanted bacteria; at the top is the watery menstruum in which the bacteria were suspended. D, Tube filled in for traversing. In the lower portion of the capillary stem is the chemotactic agent; in the upper part the column of blood. E, Tube after centrifugalisation. The bottom of the tube is occupied by the "red clot"; the intermediate portion by the "white clot," containing traces of the chemotactic agent. At the top the watery menstruum containing the bulk of this agent.

Our chemotactic agent will now traverse the column of blood and take up a position at the top, leaving behind it in the plasma traces of whatever chemical it holds in solution. That this is what actually happens, can be shown by employing, in place of a colourless chemotactic agent, a solution of methylene blue, or simple water. This last, when it follows on after a column of blood and dissolves the red blood corpuscles which this leaves in its wake, will come out at the top coloured with hæmoglobin.

The traversing procedure will be applicable in the case where we want to bring into operation chemical agents, and especially applicable where we want to bring such agents into instant application.

When we are working with a series of tubes, as will practically always be the case, it will be well to place each, as soon as it is filled, into iced water, or ordinary cold water. The buckets of the centrifuge will serve as convenient receptacles. After centrifugalisation the emigration tubes are placed in the incubator, according to circumstances, for from three to twelve hours or more. While in the incubator the tubes may conveniently be placed upright—i.e., with the white clot uppermost—in plasticine. They may also be laid on their sides, tilted a little upwards. The inverted position is to be avoided. For when we invert our tubes we bring down into the white clot a shower of red corpuscles which block emigration, and also obscure the view.

---

[1] In practice the procedure of traversing is to be carried out exactly as here described. In the illustration, Fig. 6, D, in order to convey the idea of traversing to the eye, the chemotactic agent precedes instead of following the column of blood.

Method of Bringing the Emigration Effect into View and taking Cognisance of the Results.

When all we want, is to get a general idea of what is going on in the tubes, we can obtain this by introducing the unopened tube into an observation cell. A very simple form of observation cell can be made by placing small pellets of plasticine upon each of the four corners of a microscopic slide, covering in with another slide —allowing a little overlap—and then filling into the interspace either water or some more highly refractive fluid, such as glycerine or oil. By observing in such a cell we bring into view not only the leucocytes which have emigrated into the white clot, but also those which have escaped into the interspace which may develop between the clot and the walls of the capillary tube.[2]

For all purposes of quantitative observation we blow out our clots into water, wash carefully so as to remove leucocytes adhering to their exterior, and then mount them on a slide. We then, after cutting off the surplusage of red clot, fix by drying, and stain for a few minutes in Kühne's methylene blue freely diluted. The specimens are examined, first, dry or in water, under a low power objective, and afterwards in oil under an immersion. (See Fig. 7.)

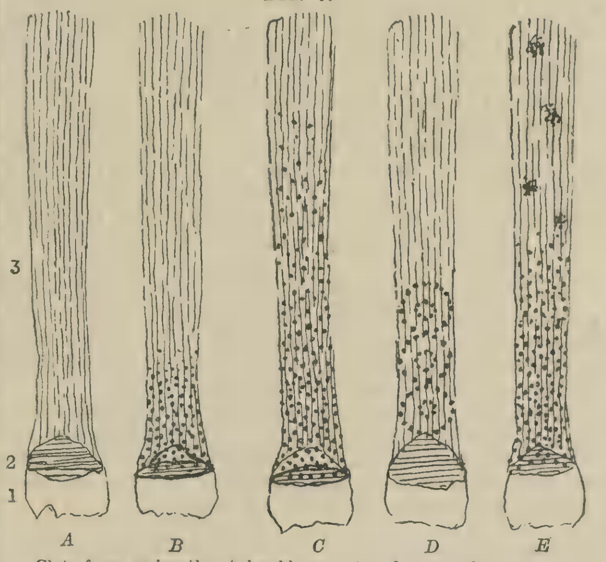
General Considerations relating to the Movements of White Blood Corpuscles.

Before passing to consider the question how it will be possible to arrive at a quantitative expression for the leucocytic movements induced by a chemotactic agent, it will be well to take a general survey of the things that present themselves to view in every emigration tube.

We have to take into account in connexion with white blood corpuscles two kinds of movements. We have, on the one hand, a process of wandering at large; and, on the other hand, a directed movement—i.e., a movement along some particular axis—undertaken under the direction of a chemical stimulus. We may call the first kind of movement an *eleutherotropic* movement. The second is usually known as a *chemotactic*—I prefer to call it a *chemotropic*—movement. It is, of course, the latter, not the former kind of movement which we are here primarily concerned to study. For clearly it is the chemotactically directed movements of the leucocytes towards the bacterial focus, and not their wanderings at large, which come into consideration in any conflict against infection.

None the less, a word may be said about eleutherotropic movements. One finds in every specimen of blood which has been simply centrifugalised and placed in an incubator, always a certain wandering at large of the leucocytes—in particular, the mononuclear white blood corpuscles, which have been tightly packed together by the action of the centrifuge and are ranged at the top of the red clot, leave their ranks and wander out into the adjacent regions of the white clot. The polynuclear leucocytes also are affected by eleutherotropic wandering. They come out from the hinder ranks of the leucocytic layer, and also from deeper down in the red clot, and wander free. In our observations we leave out of account all those leucocytes that have wandered outside the white clot. We regard them as having run to waste.

FIG. 7.



Clots from emigration tubes blown out and mounted: A, no emigration; B, compact emigration; C, dispersed emigration; D, method of enumerating leucocytes which have emigrated; E, bacterial colonies coming up only in portion of clot which has not been reached by the emigrating leucocytes.

A further point which claims attention in connexion with emigration is the *nature of the emigrating leucocytes.*

Ordinary *eleutherotropic emigration* is predominantly mononuclear, this being probably accounted for by the fact that the white blood corpuscles which are ranged up along the line which divides the red from the white clot are almost all mononuclear. In *chemotactic emigration* we have either a differential emigration of polynuclear white corpuscles, or a mixed mononuclear and polynuclear emigration in which either the one or the other of these varieties of leucocytes may predominate. In all such mixed emigrations the polynuclear, presumably because they are faster of foot, overtake the mononuclear, leucocytes and pass on and occupy the more distal portion of the field of emigration.

Method of Arriving at a Quantitative Expression respectively for "Compact" and "Dispersed Emigration."

A quantitative expression for the emigration movement which takes place in a capillary tube can be arrived at in two ways. When we are dealing with a *compact* emigration (Fig. 7, B)—that is, where the field of emigration is quite closely packed with leucocytes—we have simply to measure the area of that field, or (and this answers the purpose perfectly well) the length of clot occupied by the emigration; and we may conveniently measure it in terms of microscopic fields. In such measurements we take off from the base-line furnished by the distal border of the cone of leucocytes which occupies the base of the white clot. This represents the original leucocytic layer converted, by the contraction of the fibrin, into a cap covering the upper end of the red clot. (Fig. 7, C.)

---

[2] Attention may, in connexion with this, be called to facts which have an importance and a useful application in medicine, which happen to have also an importance and a useful application in connexion with the emigration method here under consideration. The facts I have in view are as follows. The blood of a person suffering from chilblains, or any other manifestation of a lowered blood coagulability, will, on centrifugalisation, generally fail to give the kind of white clot we require for our emigration experiments—i.e., one that is firm and non-contractile. This condition of things can be remedied by the exhibition of calcium salts, or, as the case may be, by appropriate additions of these salts made to the blood when filling our capillary tubes. I would in connexion with this emphasise that we have here brought into clear view what is the really material factor in connexion with the effect exerted by calcium salts in the blood.

And I may perhaps be permitted to point out, in connexion with my own work on calcium as an agent for promoting and citric acid as an agent for diminishing coagulability (Brit. Med. Jour., July 29th, 1893, and July, 1894; THE LANCET, Jan. 18th, 1896, and Jan. 30th, 1897), that while what I have said with reference to the clinical effects exerted has been, I believe, universally confirmed and accepted; what I have said with respect to the effect on the coagulability of blood *in vitro* has been traversed. This stands, as I believe, in relation to the fact that the laboratory workers who have repeated my work have employed methods which took into account rapidity, but left out of account firmness, of coagulation. It will now, I hope, by adopting the method of centrifugalising, and watching the effect exerted upon plasma which has been disembarrassed of corpuscles, be possible to arrive at unanimity in these matters. Finally, I may direct attention to the fact that what comes into view in centrifuged, is seen also in uncentrifuged, blood. When we make to this appropriate additions of calcium salts we obtain, as I long ago pointed out, a firmer and non-contractile clot.

When, as will happen when a longer time has been allowed for the wandering out and dispersion of the leucocytes, we have before us a *dispersed emigration* it will no longer suffice simply to measure the distance the leucocytes have travelled into the clot. It now becomes necessary to enumerate the emigrating cells. Employing first a low-power lens, we bring the upper edge of the cap of leucocytes to the extreme edge of our field of view. Then turning to our oil immersion, we bring this down upon the central portion of the low-power field, and make a count of all the leucocytes which lie within its purview—when necessary, helping ourselves out in our count. by introducing into the diaphragm of our eyepiece a cover-glass divided up by light rulings, made with a glass writing pencil. Having obtained in this way a value for the emigration in an arbitrarily selected portion of the first microscopic field, we go back to our low-power objective and move our specimen along until the objects on the extreme distal margin have been carried right across the field, and now lie just out of view on the other side. The further steps in the procedure are now simple repetition.

What are obtained by this method of enumeration are, of course, only arbitrary figures, and it will be realised that the comparative values arrived at will be strictly accurate only where we are employing clots of similar thickness.

Survey of the Data which the Method has Already Given.

We may now pass on to consider some of the data that the method has already given. White blood corpuscles will move out in any direction towards a chemotactic substance. They will, however, emigrate more freely downwards, than horizontally; and more freely horizontally, than upwards.

Anaerobic conditions are more favourable to emigration than aerobic conditions. Leucocytes will travel out further in the direction of a chemotactic substance when we absorb the oxygen in the tube with caustic alkali and pyrogallic acid and seal, than when we leave the end of the tube open to the air.

Leucocytes emigrate more abundantly in tubes standing at a temperature of 40° C. than in tubes standing at 37°. They do not emigrate at temperatures of 10° to 15°—the temperatures which prevailed on our laboratory bench. After exposure to temperatures of 0° C. for periods of half to one hour they emigrate apparently as freely as before.

Emigration apparently goes on unaffected in the presence of ether. It is abolished or suspended in an atmosphere of chloroform.

Physiological salt solution, brought into application either by traversing or by superimposing it upon the clotted or unclotted blood, induces a very vigorous emigration of polynuclear white blood corpuscles. Weaker salt solutions induce a less vigorous emigration, and water again a less vigorous. Strong salt solutions—for example 5 per cent. salt solutions—suppress emigration.

It will be appreciated in connexion with these and all findings obtained by this method, that they do not tell us the effect of reagents acting in the specified dilutions directly upon leucocytes, but only the effect of these reagents operating from a distance. In other words, our experiments do not furnish information as to what would be the effect of bringing the chemical agents in the specified concentrations directly in relation with the capillary wall.

Bacterial suspensions which have been sterilised by heating evoke, according to the dilution in which they come into application, quite different effects. The general rule applying to bacterial suspensions would seem to be as follows. Concentrated suspensions usually completely suppress emigration. Ten or hundredfold diluted, these same suspensions evoke vigorous emigration. When we employ progressively higher dilutions we arrive in time at a point when the effect of the bacterial suspensions is exactly the same as those of the articular fluid which we are employing as a diluent.

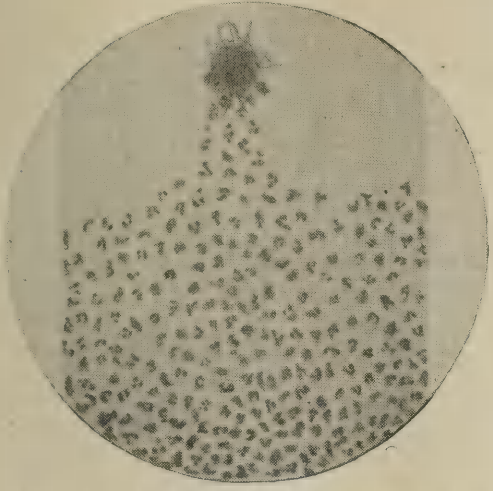
Normal bloods tested with one and the same series of bacterial suspensions exhibit quite different degrees of chemotropic sensibility. Chemotropic sensibility, not alone to bacterial suspensions but also to physiological salt solution, is very strikingly modified in the case of patients suffering from bacterial infections. The same applies to persons inoculated with streptococcic vaccines. In five out of six men, inoculated with such a vaccine and examined both before and afterwards, the emigrating response to streptococcus was subsequently to inoculation very strikingly increased. In the case of one man it was diminished.

Results somewhat similar to those obtained with dead cultures are obtained with suspensions of living microbes (streptococci and gas phlegmon bacilli), but here the prolonging of the incubation period may strikingly alter the situation.

What generally happens may be summed up as follows. When, by superimposing and centrifuging, a heavy sowing of microbes has been implanted into the unclotted blood, the colonies come up all along the white clot, and emigration into this is completely checked. Where only a moderate implantation of microbes has been made, we have in different parts of the clot different results:—Bacterial colonies develop freely in the distal area of the clot which is not invaded by emigration. In the intermediate region—that is, in the region where the microbes can grow out before the leucocytes arrive—one sees with the low-power objective areas specially crowded with leucocytes—these are in point of fact colonies which are being broken up and dispersed by invading leucocytes (Fig. 8);—and with the oil immersion one sees that every leucocyte in these crowded masses is taking up microbes, and that there is also in all this region of the clot plentiful phagocytosis of scattered microbes. (Fig. 9.) In the base of the white clot—i.e., in the area where emigration has occurred earliest and most vigorously—one finds absolutely no trace of microbial growth.

The appearances which have just been described correspond, of course, to a period of conflict. This conflict is generally at its most interesting phase in tubes which have been incubated from three to six hours. When we come later—for instance, after 12 or more hours—the conflict is over. We then find either that the white corpuscles are masters of the field, and the microbes have disappeared, or else that the microbes have invaded the whole clot, and that this crumbles away as soon as it is blown out into water. There can be little doubt that the crumbling away of the clot, and the overrunning of the blood with microbes are due to the digestion of the fibrin, and the corruption of the blood fluids by trypsin set free from the disintegrated leucocytes.

FIG. 8.



Extreme limit of emigration, showing phagocytes attacking streptococcus colony.

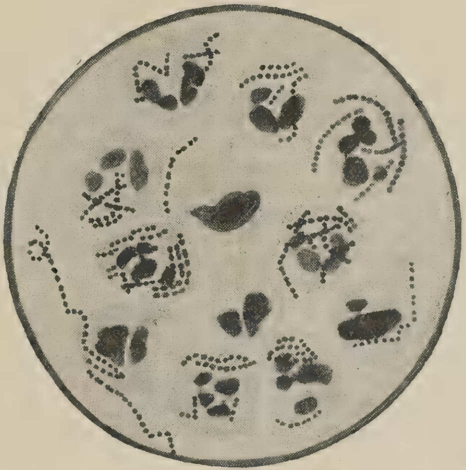
Experiments such as these just outlined in which living microbes are brought into application on blood provide in point of fact a valuable test method. They tell us the resultant of the *chemotropic sensibility* of the leucocytes, the *opsonic power* of the blood fluids, the *digestive capacity* of those phagocytes which come into action, and of the *antitryptic* and, where such comes into account, the *bactericidal* power of the blood fluids. We are, in fact, furnished with something like a complete evaluation of the antibacterial powers of the blood.[3] There is still one element left out of account. The test method here in question does not tell us anything as to whether or no there are bacterial poisons in solution in the blood fluids of the infected man. But this is a question which can be separately investigated. I have tried to find the answer by traversing normal bloods with the sera derived from patients suffering from septicæmic infections. And I have by this procedure obtained in a series of cases what appeared to be a definitely chemotropic emigration.

All that has been recounted above is, of course, only a very small beginning. But I think we may be confident that the method for the study of emigration which has here been proposed will resolve important problems in connexion with infection generally, and also—and this is what specially concerns us here—some of the problems in connexion with wound infections which are now urgently pressing for a solution.

In the matter of general problems of infection it would, I think, be possible, by implanting bacteria into blood in combination with chemical agents which would respectively promote and hinder emigration, to resolve for each particular bacterial infection, the question as to whether it is the leucocytes or the blood fluids which come most into consideration as destructive agencies. That problem once resolved, we should know whether we ought in the infection in question to direct our chief efforts to increasing the efficacy of the blood fluids, or to modifying the chemotropic sensibility of the leucocytes and encouraging emigration.

Again, it looks as if it might be possible by very simple experiments to resolve the problem as to why in gonorrhœa, and also in other surface infections, the purulent discharge is suddenly arrested when the microbes succeed in invading the blood stream, or establishing themselves in an articulation or elsewhere in the interior of the body. It would seem possible—for something of this sort would seem to occur in septicæmias supervening on wound infections—that we may be dealing here with a paralysis of the emigrating powers of the leucocytes. Or, again, it is possible that in these cases emigration may be simply suspended by a redistribution of the chemotactic forces. In other words, the cessation of the external discharge may simply mean that there is now in the blood a bacterial poison; and that this chemotactic element, acting upon the leucocytes as a *vis a tergo*, counterbalances the *vis a fronte* of the chemotactic substances produced by the bacteria on the external surfaces.

FIG. 9.



Phagocytosis of streptococcus towards extreme limit of emigration.

In connexion with the particular problems of wound infections we may hope at no distant date to come into possession of information which will enable us to activate or restrain, according as the one or the other may approve itself the better policy, the emigration of leucocytes into the wound. And we may hope also to determine in connexion with every antiseptic or other solution which is brought into application in a wound, whether it promotes or hinders emigration.

Finally, let me point out—for everything that concerns bacterial vaccines concerns the treatment of wound infections—that experiments on emigration will almost certainly resolve a number of important outstanding questions in connexion with vaccines. They ought very easily to resolve the question as to what is the best excipient for a vaccine—whether a menstruum which would restrain emigration, or one, like physiological salt solution, which would call forth a vigorous emigrating response at the point of injection. And lastly—and this would be one of the most important applications of observations on emigration—we ought to be able to determine what is in the case of each bacterial vaccine the dose which will induce the earliest possible and the most effective determination of phagocytes to the focus or foci of infection.

---

[3] It will be observed in connexion with tests thus conducted with centrifuged blood that, if we leave out of regard the centrifugalisation, they are in all essentials the same as the *phagocyto-bactericidal* tests with freshly drawn uncentrifuged blood which I have already described (Vaccines and Drugs in Pneumonia, Constable, 1914).

(*To be continued.*)

ON THE PENETRATING POWER OF THE X RAYS FROM THE COOLIDGE TUBE.

BY SIDNEY RUSS, D.Sc.

A Coolidge X ray tube having been acquired by the electro-therapeutical department of the Middlesex Hospital, Mr. C. R. C. Lyster requested me to make some measurements of the radiation emitted from it, preparatory to its being put into clinical use. The results of a first systematic series of tests upon it were communicated to the February meeting of the Roentgen Society. The leading features of the observations were: (1) The recognition that the unscreened radiation from the bulb was heterogeneous, consisting of "soft," "medium," and "hard" rays; and (2) the relatively larger production of "hard" rays than of "soft" rays when the heating current, regulating the cathode stream, was increased.

Since the meeting referred to, the observations on the bulb have been continued with two objects in view—first, to measure the hardness of the rays which would be used clinically (for superficial and for deep-seated conditions); and, secondly, to find how nearly the most penetrating rays given out from the bulb approach the penetrating power of the hard gamma rays from radium. It was assumed that for superficial conditions unscreened "soft" and "medium" rays would be used, and that for deep-seated conditions the rays would be heavily filtered by aluminium; accordingly measurements were made of the character of the rays under these circumstances. This was done by finding how the intensity of the beam of X rays was reduced on interposing sheets of aluminium between the bulb and a small gold-leaf electroscope used to measure this intensity.

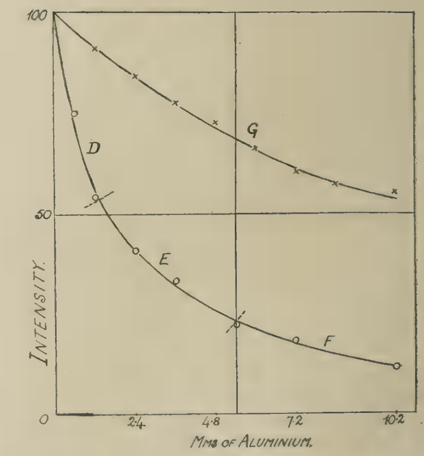
When measuring the unscreened rays the bulb was run under a moderate sparking distance (3 cm. between spheres 5 cm. in diameter, corresponding to about 11 cm. between points). The gradual reduction in the intensity of the radiation as increasing thicknesses of aluminium are interposed is shown in Curve 1, Fig. 1. When this curve is analysed it is found to consist of approximately three portions, which may be considered as Section D, in which the rays are "soft" and therefore easily absorbed; Section E, where they are rather more penetrating; and Section F, where they are considerably "harder." The beam is, as stated, heterogeneous.

The observations upon heavily screened rays were made as follows. For the same heating current as before the spark-gap was increased to nearly the limit of the coil (viz., 10 cm. between the spheres or 30 cm. between points) and the rays were screened by 7 mm. of aluminium. The character of the rays which penetrated this filter was found in the manner described, and the absorption suffered in going through various thicknesses of aluminium is shown in Curve 2 of the same figure. Analysis of this curve shows that the rays are very hard and practically of a homogeneous nature.

The introduction of as much as 7 mm. of aluminium for the purpose of screening effects a considerable reduction in the intensity of the rays, but, granted that at least 3 or 4 mm. are necessary, it remains to determine whether the extra amount of aluminium, by which homogeneity is attained, entails too large a reduction in the quantity of rays available for use; the beam is not quite homogeneous with 4 mm. screening. Actually it is found that this extra 3 mm. entails a diminution of nearly 25 per cent. in the intensity of the beam already screened by 4 mm. of aluminium. Apart from any desirable physiological effects which the hardest X rays may give rise to, the use of a homogeneous beam ensures the most uniform irradiation throughout the tissues that is possible, assuming that such application has to be made externally; moreover, it allows of an accurate determination of the strength of the radiation at any particular depth of tissue.

The results represented in Fig. 1 were obtained by using aluminium as the absorbing substance for the rays; this is a matter of convenience, for the pure material is obtainable in sheets of any required thickness. When it is desired to apply the data to determine the gradual loss of intensity of X rays as they make their way through the tissues certain precautions are necessary. If we consider that the tissues of the human body have on an average about the same density as water, then if we knew the relative transparency of water and aluminium for X rays of any specified quality we could gauge the absorption which the tissues would exercise upon any particular beam of X rays.

FIG. 1.



When experiments are made to determine this relation between water and aluminium it is found that in the case of soft X rays water (and therefore tissues also) absorbs them much less than its density would suggest, actually about one-fourth part; hence, since aluminium is 2·7 times the density of water, 1 mm. of aluminium absorbs as much 4 × 2·7 = 10·8 mm. of tissue. As one passes to rays of a more penetrating character water becomes relatively to aluminium a better absorber, and when the homogeneous rays transmitted through 7 mm. aluminium are reached, the factor 1/4 has reached 3/4, so that 1 mm. of aluminium is now equivalent to 4/3 × 2·7 = 3·6 mm. of tissue.

The data are now available for calculating the degree to which the dose of X rays administered varies from point to point in the tissues. As an illustration of this we may consider the case of some condition being treated by X rays screened in the manner indicated. Let it be assumed that the thickness of tissue is 16 cm. and that the surface of the skin is 20 cm. from the anode—the data in the accompanying table show what the intensity would be at different depths below the surface, the gradual diminution being due to two causes—increase in distance from the anode and absorption of the rays by the superimposed tissues, both of which are taken into account in the data given. Column (*a*) represents the fall in intensity where the radiation is in one direction, and column (*b*) when the direction is reversed. The total in column (*c*) shows the variation throughout the tissues when the radiation is reversed in the manner indicated.

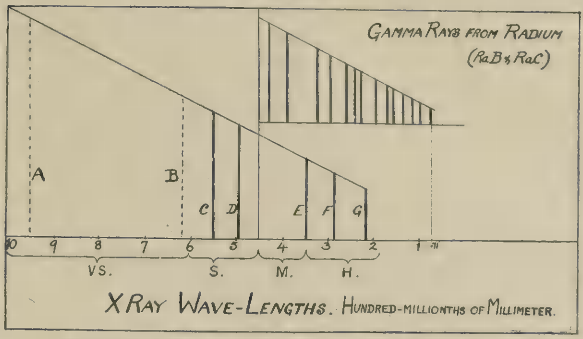
Depth below surface.	Intensity of rays. (*a*)	(*b*)	Total. (*c*)
0	100·0	1·8	101·8
2 cm.	57·6	2·8	60·4
4 ,,	33·8	4·5	38·3
6 ,,	20·0	7·2	27·2
8 ,,	12·1	12·1	24·2
10 ,,	7·2	20·0	27·2
12 ,,	4·5	33·8	38·3
14 ,,	2·8	57·6	60·4
16 ,,	1·8	100·0	101·8

The question as to how nearly the X rays approach in penetrating power that of the hard gamma rays of radium cannot be answered without specifying the substance which is used to test the penetrating power. For example, if we make a comparison in this respect for lead we find that the X rays emitted from the Coolidge tube, under a spark-gap of 30 cm. (points) and screened by nearly 2 mm. of lead and 7 mm. of aluminium, have about one-thirtieth of the penetrating power of hard gamma rays. If, however, the comparison be made with aluminium under the same conditions, the X rays have a penetrating power of nearly one-fifth of that of the gamma rays, and nearly one-fourth if the comparison be made with water (tissues).

These observations do not preclude the possibility of still more penetrating X rays being produced, but under the conditions specified the above figures represent what holds for the main part of the radiation; if harder X rays are present they do not contribute more than about 1 part in 50 to the effects associated with the heavily screened radiation. By the term "hard gamma rays" is meant the radiation emitted from radium enclosed in a platinum tube 1 mm. thick, the softer secondary rays from the platinum itself being absorbed by 2 mm. of aluminium.

The investigations initiated by Lane in 1912 have been pursued in this country by W. H. Bragg and W. L. Bragg and by Moseley and Darwin, proving conclusively that the X rays are ether vibrations, and many determinations of the wave-length of certain specified rays have now been made. The two latter investigators have shown that the wave-length of an X ray may be inferred if the extent to which the ray is absorbed by some substance, such as aluminium, is known. There is a simple relation between the coefficient of absorption and the wave-length as long as one is not considering regions exhibiting selective absorption. We may make use of this relation to find the average wave-length of the different components constituting the heterogeneous beam whose absorption is represented by the curve (Fig. 1). Dividing this into sections in the way that analysis suggests that it should be done, it will be found that the wave-lengths for the three sections D, E, and F are 4·85, 3·43, and 2·84 × 10^{-9} cm. respectively, and these are represented by the vertical lines on the lower diagram of Fig. 2, the length of the line being drawn proportional to the wave-length. Line C is obtained as a result of measurements with a very soft bulb (about 6 cm. spark-gap), and line G with a wave-length of 2·14 × 10^{-9} cm. represents the homogeneous very hard X rays obtained under the conditions already specified. On the same diagram are inserted two wave-lengths, A, B, which correspond to part of the characteristic radiation emitted by platinum and rhodium. The data for them are taken from "X Rays and Crystal Structure" (1915), by W. H. Bragg and W. L. Bragg. An inset in Fig. 2 shows the wave-lengths of the gamma rays emitted by radium (RaB and RaC) as determined by Rutherford and Andrade (*vide Philosophical Magazine*, August, 1914).

FIG. 2.



VS. = very soft. S. = soft. M. = medium. H. = hard.

The representation in this manner—viz., C–G—of the different varieties of X rays must not be taken to mean that the rays emitted consist of homogeneous portions; the radiation is much more akin to white light, but certain regions appear homogeneous when tested by the method of absorption. The subdivisions "very soft," &c., are quite arbitrary, and done for the purposes of the present article. It is hoped that the Dosage Committee of the Roentgen Society will make certain recommendations on this subject in the near future.

A comparison of the two sets of wave-lengths shows that the wave-length of the very hard X rays (deduced from their absorption by aluminium) is about three times that of the shortest gamma ray measured by Rutherford and Andrade. With regard to the possibility of producing X rays with the same wave-length as the hardest gamma rays, it would seem that the advent of the Coolidge tube should bring this realisation nearer than experience with the ordinary focus-tube suggested.

There is a tendency towards the more extensive use of hard screened X rays. This brings with it the consideration that the operator is subject to an increasing amount of stray radiation. The yield of X rays from modern bulbs is a very large one, and the question of protection of all those engaged in the administration of the rays becomes an increasingly difficult one.

NEW THEORIES AND INVESTIGATIONS CONCERNING PELLAGRA.

By ALBERTO CENCELLI,
SENATOR; PRESIDENT OF THE PELLAGRA COMMISSION OF ROME.

(*Specially Translated for* The Lancet.)

Pellagra is, without doubt, one of the diseases that for more than a century have been the subject of discussion both with Italian and foreign doctors. This complaint, which not only carries off countless victims, and robs agriculture of many able-bodied workers, as well as filling hospitals and lunatic asylums, is not yet vanquished. Men of science are in continual disagreement with one another, and have not yet decided upon the nature of pellagra and its determining cause, far less have they been able to point out the measures to be adopted for its cure and prevention.

Until comparatively recently, maize was generally considered to be the cause of the disease, and it was thought from the investigations first of Sette and Balardi, and subsequently of Lombroso and his school, that it was probably due to (1) the insufficient nutritive value of this cereal; (2) toxic substances found in sound or in spoilt maize; (3) special toxins produced by certain moulds which develop in maize under particular conditions; (4) the increase in virulence of Bacillus coli in the intestine attributable to a maize diet, although the corn is in good condition; (5) the action of definite pathogenic agents introduced into the organism at the time of the ingestion of the maize. Upon these principles and theories are based all the Italian legislative measures for the prevention and cure of pellagra. But the very numerous facts recorded by many scientists in Italy and other countries who have studied the question thoroughly and with much devotion, have proved that maize can no longer be regarded as the sole and specific cause of the disease.

Briefly summarised, the facts are as follows: There are many sufferers from pellagra who have *never* lived on maize; entire districts in Italy (Molise, Campania, Basilicata, Calabria, Liguria) and abroad (Brazil) where good, mediocre, and bad maize are used to an extraordinary degree, in fact almost exclusively, are free from the disease, while in some provinces and communes where pellagra is common, immune zones exist, the latter being clearly marked off from the infected areas, although the climatic, economic, hygienic, and dietetic conditions are identical, and maize is the staple article of food. In a family where the members must more or less have inherited the same tendencies, and are subject to similar hygienic and dietetic conditions and to the effects of equally excessive toil, one or two (rarely more) sicken.

The prophylactic and curative measures hitherto adopted, and which were based upon the maize theory, have in truth yielded but little result. The amount of foreign maize (which is considered the most to be feared) imported into Italy has no effect upon the increase or decrease of pellagra. In spite of the *absolute* abolition of this cereal as an article of diet the disease may continue to show itself with progressive symptoms for many consecutive years.

An English commission, with Dr. L. W. Sambon at the head, which has made a special investigation of pellagra also in Italy, has decided that there is no connexion whatever between maize and pellagra, and has put forward the hypothesis that the disease must be attributed to a parasitic protozoon which is probably transmitted and propagated by a species of mosquito (similium) existing in the drinking water.

Professor Giulio Alessandrini, of the University of Rome, is also a decided opponent of the maize theory. By means of a series of studies and diligent observations prosecuted by himself in almost all the pellagra districts of Italy[1] he has, he believes, established that this malady owes its origin to an exactly localised *quid* found in drinking water, and only in such waters as arise in, or traverse, or are stagnant on, argillaceous soil. Professor Alessandrini has been led to this conclusion from the observation of the following facts: (1) The entire absence of pellagra where clear running water is drunk; (2) the presence of the disease where stagnant water is used or that from ditches or wells in the superficial stratum; (3) the gradual, slow disappearance of the disease where drainage operations are gradually and slowly carried out; (4) the rapid disappearance of the malady where aqueducts are made or where many artesian or other deep wells are sunk at the same time, or where the existing bad wells are put into good condition; (5) the obstinate persistence and even progressive increase of the complaint when nothing has been done as regards the drinking water; (6) the restriction of pellagra in those districts where the water is good, to such persons as have, through emigration, contracted the disease where it is unwholesome; (7) the greater and almost exclusive occurrence of pellagra in country districts, especially in those which are the most thickly populated, and where nothing is done to improve the condition of the water used for drinking purposes. In consequence of these new views, and at the instigation of Parliament, the Ministry of the Interior nominated a commission for the purpose of examining and controlling these new theories, in order to ascertain if it was necessary to change or to modify the present Italian legislative measures regarding pellagra. So far, however, this commission has presented no report.

The above-mentioned investigations of Alessandrini having become known, I thought it well in June, 1912, that the Pellagra Commission of the Province of Rome, of which I have the honour to be President, should request Professor Alessandrini (who is a member of the said commission), together with Professor Giannelli and Professor Filena, to make an inquiry in our province for the purpose of ascertaining the condition of the endemic disease of pellagra in Lazio and to investigate the conditions which directly or indirectly have an influence upon the development of the malady according to both the old and new theories. The report,[2] after having established that pellagra in Lazio is only met with in four districts, and in a limited number of persons (35 women and 11 men), states that also among our own people the disease can, and in fact does, exist where maize is not used; further, that in some districts, it is only met with in the centres of population, while it is absent in the country, and that some of the peasants only fall ill when, from the necessity of finding work, they go to certain districts without, however, making any change in their food or conditions of life.

The conclusions reached are the following: In the province of Rome there seems to be no connexion between a maize diet and pellagra; the disease is circumscribed and is always confined to determined localities; there may be some connexion between the drinking water and the malady; there is apparently none between sucking insects and pellagra. The water hypothesis of Alessandrini, although based upon endemic data of indisputable value, needed, however, strict experimental control. Professor Alessandrini himself initiated at the Institute of Hygiene of the University of Rome a few experiments, the results of which being favourable to his theory, encouraged him to continue his researches upon a larger scale.

---

[1] La Pellagra in Italia, Osservazione epidemiologiche, Annal d'Igiene sperimentale, Roma, 1910.

[2] Il Policlinico, vol. xx., 1913.

It appeared to me and to the Pellagra Commission of Rome that these preliminary studies and experiments carried out by Professor Alessandrini (with whom was subsequently associated Professor Alberto Scala, who attended to the chemical side of the question) were of great scientific importance. The new views, if widely controlled and confirmed, might definitely solve the questions of the origin and cure of pellagra. Therefore I did not hesitate to propose to our Commission that the necessary means should be placed at the disposal of the two investigators for the extension of their researches and studies and their experiments on animals. The Commission approved of this suggestion.

Already in May, 1913, Alessandrini and Scala gave a verbal report of the latest results of their labours and the conclusions they considered could be drawn from them. Now they have published a detailed monograph, "Contributo nuovo alla Etiologia e Patogenesi della Pellagra,"[3] in which they give an account of their experiments on man and animals and discuss the definite conclusions they have reached.

The statement already made by Alessandrini and mentioned above was confirmed—viz., that pellagra is contracted in definite zones where the usual drinking water comes from springs arising in argillaceous soil or from the streams and stagnant pools in a clayey district.

The new and important point which has just been established is the cause of the disease. This appears to be a chronic poisoning brought about by the silica in colloidal solution in waters of determined composition; in other words, pellagra seems attributable to mineral colloids. According to the authors, the clay is the first cause of the evil, for the rain-water present, either in the superficial or the deep strata of the ground, reacts upon the clay which is a silicate of alumina, producing a hydrolysis that brings about the formation of silicic acid and hydrate of alumina. Both these compounds, from the condition under which the hydrolysis takes place, can pass into the water in the colloidal form. Since, as is well known, there exists an incompatibility between colloidal silica and colloidal alumina, there only remains in the water the amount of silica in excess of that required for the precipitation of the alumina. The colloidal silica-alumina compound, which must on no account be confused with silicate of alumina, goes to form the deposit. Part of it, however, remains in suspension as a very finely divided colloid, and is the cause of the persistent opalescence often observed in the water drunk by sufferers from pellagra. The poisoning by silica would thus resolve itself into a mineral acidosis upon which would depend all the anatomical, pathological, and metabolic alterations which are met with in pellagra patients. Hence arose the other conclusion regarding pellagra—viz., that it is a disease due to the enforced retention of mineral salts followed by a liberation of acids which is excessive in comparison with the amount regarded as normal in the case of any given organism.

It having been proved that the question is one of mineral acidosis, Scala and Alessandrini believed that the toxic effects could be modified by the injection of an alkaline substance such as trisodium citrate. They also considered that the pellagra-inducing water could be corrected and freed from injurious substances by placing small pieces of lime in the pipes and reservoirs.

In the monograph cited above are described numerous experiments in inducing pellagra in monkeys, dogs, guinea-pigs, and rabbits, either by mixing a small quantity of the water from the pellagra zone with the usual food of these animals, or by means of intraperitoneal and subcutaneous injections of colloidal or gelatinous silica, or by introducing the same substances through their mouths. The results have always agreed, both as regards the symptoms and the pathological, macroscopical and microscopical changes. The clinical complex corresponds exactly, or almost exactly, with that of pellagra in the human subject.

The curative treatment was not only applied to animals in which the disease had been induced, but also to human beings who had been suffering from pellagra for longer or shorter periods of time. As it was a question of an absolutely innocuous substance such as trisodium citrate, the experiments could be carried out without hesitation. The results were in the highest degree satisfactory; persons who had been ill for a long time improved and were cured in a relatively short space of time without any change having been made in their mode of life, surroundings, or diet.[4] The Pellagra Commission of Rome wished that these curative experiments should be largely extended both in its own district and in the other provinces of the kingdom where this disease is most prevalent. Further, it has carried out, at its own expense, the correction of the water by means of the introduction of pieces of lime in the commune of Onano (Viterbo), which is the part of Lazio where pellagra has always been persistently endemic. The aqueduct has been completely restored, and all possible sources of contamination have been removed, while a number of minute pieces of calcium (previously well washed) have been introduced into the reservoir and along the channel. This will afford a decided proof of the course to be taken in prophylactic measures against pellagra.

---

[3] Tipografia Nazionale Bertero, Rome, 1914, pp. 176 and 8 coloured plates. THE LANCET, Sept. 12th, 1914, p. 713.

[4] The following are the exact words in which the two eminent scientists have recorded their results:

1. Silica in a colloidal condition and in a gelatinous condition produces chronic poisoning in guinea-pigs, rabbits, dogs, and monkeys when administered by means of subcutaneous or intraperitoneal injections, or when introduced into the mouth. 2. The electrolytes with which the silica comes in contact before entering the circulation have a great effect upon its toxic action, for which reason colloidal compounds or compounds of superficial absorption are made which may be more or less harmful than silica alone, or perfectly innocuous, as in the case of carbonate of calcium. 3. The action of alumina is similar to that of silica, at all events on guinea-pigs and rabbits, and thus increases the effect of the former substance, whether it unites with it in the form of a colloid mixture or whether it is merely in suspension in the water and separate from the silica. 4. The water of the pellagra zones of the Gualdo Tadino district (a subdivision of Grello and Morano) containing argillaceous matter in suspension, when mixed with bran and administered through the mouth to guinea-pigs and rabbits and as a drink to monkeys, produces the same silica poisoning. 5. The feeding on maize-flour and grass of animals subjected to the action of silica in no wise increases the toxic action, except in such cases where the maize introduces poisonous silica, or any other injurious substance. 6. The silica is the cause of the retention of the salts and gives rise, first to an excessive fixing of mineral salts in the tissues and later to the excessive liberation of mineral acids which produce the anatomico-pathological lesions already recorded. 7. The effects of this toxic action are counteracted by intramuscular or subcutaneous injections of solutions of neutral citrate of sodium as an alkalising agent. 8. The complex of toxic symptoms produced by the silica in animals is most similar to, if not identical with, that of human pellagra. 9. Human pellagra is an acidosis, as has already been demonstrated, and is proved by the fact that patients suffering from this disease are cured, or their condition is greatly improved, by the use of neutral citrate of sodium; that is to say, they are cured when the malady is of relatively recent date or when the free mineral acids have not caused irremediable lesions, as must occur in toxic action of long standing. 10. In animals rapid poisoning can occur, which, however, introduces no new features. The same is also the case in acute human pellagra.—Contributo Nuovo, cit., pp. 168 et seq.

Let us hope that the results hitherto obtained may be indisputably confirmed. Pellagra would then be vanquished by very simple and inexpensive means.

DIFFERENTIAL DIAGNOSIS BETWEEN ACUTE ABDOMINAL AND CERTAIN ACUTE INTRATHORACIC DISEASES.

By COLIN MACKENZIE, M.A., M.D., B.C.Cantab., F.R.C.S.Eng.,

LATE RESIDENT SURGICAL OFFICER, ROYAL INFIRMARY, BRADFORD; LIEUTENANT, R.A.M.C. (CIVIL SURGEON), BRITISH EXPEDITIONARY FORCE.

Introduction.

The knowledge that intrathoracic disease may be accompanied by signs of abdominal disease is at least a century old. Thus Laennec in his admirable treatise in 1819 says of pneumonia that though it is unusual for the epigastrium to be painful, yet in those patients who suffer pain in the stomach it is hard to say whether the pain is produced by pressure or from the impediment thereby occasioned to respiration. Andral in 1823 must have seen several such cases, for he states that though in many cases of pleuro-pneumonia "the abdomen is soft and free from pain," there may be (1) hypochondriac pain with nausea and hiccough; (2) pain in the flank and vomiting; (3) sudden pain in the epigastrium; and (4) nausea and vomiting. Louis in 1829 observed pain in the abdomen in a quarter of his cases which died from pneumonia, but he says that pain in the abdomen was only observed in those patients with pneumonia who were suffering from diarrhœa. He observed gastric pain, or vomiting or nausea in 40 out of 82 pneumonic patients. Though Wilson Fox observed that abdominal pain was rarely an initial symptom of pneumonia, the rapid advance of abdominal surgery and the consensus of opinion as to the advantages of early operation have brought this type of case into prominence. Crozer Griffith in 1896 described a case of pneumonia in a child which closely simulated an attack of appendicitis.

In 1902 Maurice Richardson published six cases of pneumonia which were at first diagnosed as cases of appendicitis, and by one of those not uncommon coincidences H. Barnard read a paper on the same subject before the Clinical Society of London on the next day. The latter said that the abdominal signs and symptoms which resulted might be divided into two classes: 1. Parietal, where the abdomen is tender, rigid, associated with painful costal respiration, and spasm of the recti. These signs are generally one-sided, and often in the right or left iliac region. 2. Visceral, where nausea, hiccough, or vomiting is present. The vomiting may be urgent and bilious. Distension may be present. Constipation is usually concomitant. He explains these signs thus: (*a*) That the irritation in continuity of the lower six dorsal nerves may cause abdominal hyperæsthesia and spasm; (*b*) that referred visceral pain explained abdominal pain in those cases of early pneumonia which did not involve the pleura. That visceral impulses passing into the root ganglia of dorsal nerves 7, 8, and 9 exalted their excitability so that impulses from the skin to those ganglia gave rise to painful impressions (Head); and (*c*) visceral signs must be explained by some reversal of the reflex, or by direct involvement of the splanchnic nerves (dorsal 6 to 12) above or below the diaphragm.

On the other hand, C. W. G. Rohrer considers that abdominal pain, especially in children, is often due to inflammation of the diaphragm itself. Pye-Smith and Beddard state that in cases of pneumonia, pain in the side and abdomen is frequently an early sign. "It is due to pleurisy and is therefore absent in deep-seated pneumonias." As stated above, Henry Head believes that the occurrence of abdominal pain in deep-seated pneumonias may be due to referred visceral pain, and I shall quote some cases where as the definite signs of pneumonia were so late in appearing, and there were no signs of pleurisy, the pneumonia must have been deep-seated. Musser and Norris found abdominal pain in only 13 cases out of 1129 cases of pneumonia—that is, in 1·1 per cent. of cases, and vomiting in 192 cases out of 1328 cases of pneumonia—that is, in 14 per cent. of cases. J. W. Chatard observed abdominal pain in 51 cases out of 658 cases of pneumonia—that is, in 7·7 per cent. of cases.

An investigation into the registers for 1910 and 1911 of a metropolitan hospital (the Middlesex) reveals the fact that out of a total of 100 cases of pneumonia 6 cases were admitted into surgical wards as cases of acute abdominal disease. Of these cases, one underwent laparotomy and the others were transferred to medical wards. A case of pleurisy was also admitted into a surgical ward. During this period 4 cases of pericarditis and 1 case of endocarditis were admitted to surgical wards as acute abdominal cases, and of these 5 cases, 4 underwent laparotomy.

Differential Diagnosis.

The most common acute intrathoracic diseases which may simulate acute abdominal diseases are lobar pneumonia, pleurisy, and pericarditis. I propose to deal with these three diseases in this order, and then briefly to enumerate the various abdominal conditions which they may simulate, mentioning any special points in the differential diagnosis, &c., peculiar to each disease.

A. *Lobar Pneumonia.*

In the differential diagnosis of pneumonia careful consideration must be given to the pulse-respiratory quotient, the temperature, the character of the pulse, the presence or absence of herpes, the colour of the face, the feel of the skin, and the examination of the rectum.

The pulse-respiratory quotient.—I have consulted the charts and notes of all cases of pneumonia and of acute abdominal diseases in the registers of the Middlesex Hospital during the years 1910 and 1911. I have rejected all cases which came in later than 48 hours after the onset, and have taken as the standard the pulse, respirations, and temperature as charted four hours after admission, when I hoped that the influence of transport to the hospital would have ceased. In many of the acute abdominal cases I have had to content myself with taking the pulse, respirations, and temperature charted immediately prior to operation. I have taken the average of the totals and noted any cases which differed to any extent from the average.

Summary of Averages of Cases of Pneumonia in 1910 and 1911.

Year.	—	No. of cases.	Pulse.	Respiration.	Quotient.	Temperature.
1910	Children with broncho-pneumonia.	37	134·0	48·0	2·8	102·4°F.
1911	,,	17	136·0	51·0	2·6	102·8°
1910	Children with lobar pneumonia.	19	134·0	48·8	2·7	103·0°
1911	,,	12	127·0	48·2	2·65	103·0°
1910	Adults with pneumonia (lobar).	39	112·0	40·2	2·77	102·8°
1911	,,	30	115·0	41·0	2·8	103·0°

Summary of Averages of Acute Abdominal Cases.

Year.	—	No. of cases.	Pulse.	Respiration.	Quotient.	Temperature.
1910	Children with acute appendicitis.	4	111·6	28·0	3·9	99·8°F.
1911	,,	4	107·0	27·5	3·88	100·3°
1910	Children with appendix abscess.	6	117·0	31·0	3·7	100·6°
1911	,,	8	120·2	27·4	4·3	101·7°
1910	Children with general peritonitis (appendix).	3	114·6	29·0	3·9	101·4°
1911	,,	2	110·0	28·0	3·9	99·8°
1910	Adults with acute appendicitis.	53	100·2	23·3	4·3	100·0°
1911	,,	30	101·0	23·4	4·3	100·5°
1910	Adults with appendix abscess.	30	91·3	23·6	3·86	100·0°
1911	,,	37	102·4	25·0	4·1	100·7°
1910	Adults with general peritonitis (appendix).	15	123·0	27·1	4·5	100·6°
1911	,,	12	112·5	28·0	4·0	101·0°
1910	Adults with general peritonitis.	16	122·0	31·0	3·9	98·5°
1911	,,	13	104·8	28·5	3·7	99·6°

It will be observed from the summaries that the averages were practically the same in each year, and that the average quotient was therefore remarkably constant. On these figures one might formulate this dogma. "In cases where there is doubt as to whether the lungs or the abdominal viscera are responsible for the symptoms, a pulse to respiration quotient of under 3 would decide in favour of the former, and of over 3, of the latter." Unfortunately exceptions are numerous. In the statistics for 1910 and 1911, from which the average was made, there were the following exceptions:—

Children with broncho-pneumonia.—The total number of cases was 54. The number of exceptions was 10, so that exceptions to the above rule equal 18 per cent. The highest pulse to respiration quotient was 5. In 8 cases of these 10 the quotient sank to well under 3 within two days of admission.

Children with lobar pneumonia.—The total number of cases was 31. The exceptions numbered 4, which exceptions to the above rule equal 13 per cent. The highest quotient was 4. In all these cases the quotient became less than 3 within 48 hours.

Adults with pneumonia.—The total number of cases was 69. The exceptions were 18, which exceptions to the above rule equal 26 per cent. One of these exceptions showed as high a quotient as 4. In 14 out of the 18 exceptions the quotient became less than 3 within 48 hours.

If now the quotients of the acute abdominal crises be examined—

Children for 1910 and 1911: The total number of cases was 27, and there was not a case where the quotient was less than 3.

Adults for 1910 and 1911: Total number of cases 206. The number of cases where the quotient was less than 3 was 5, which is equal to an exception of 2·4 per cent. to the statement that the respiratory-pulse quotient in abdominal crises is never less than 3.

It is very interesting to note that every one of these exceptions was a case of general peritonitis. In four cases out of the five the peritonitis was due to perforation of a gastric ulcer, so the probability is that the diaphragmatic peritoneum was involved. The other exception was due to a gangrenous appendix. Two of these cases subsequently developed pneumonia. With the onset of pneumonia the quotient sank from under 3 to 2.

To summarise the results of the investigation of the respiratory-pulse quotient, the quotient in cases of pneumonia is practically always less than 3 within 48 hours, while the quotient in cases of acute abdominal crises is never less than 3 unless the subphrenic peritoneum is infected. Even where this complication has arisen a quotient of less than 3 is exceptional.

Temperature.—On comparing the average temperature of a case of pneumonia with the average temperature of an acute abdominal case a striking difference is seen. In cases of pneumonia of children the average temperature is 102·6°. In acute abdominal cases among children the average temperature is 100·4°. In cases of pneumonia among adults the average temperature is just under 103°. In acute abdominal cases of adults the average temperature is 100·4°. It is very striking that the average temperature of 29 adults admitted with general peritonitis (due in most cases to perforation of stomach or duodenum), was only 99°. Of these general peritonitis cases the highest recorded temperature prior to operation was one of 104° in a case of criminal abortion, while two cases of perforated gastric ulcer admitted two days after perforation had a temperature of 102°. Out of 29 cases of general peritonitis not due to the appendix 10 cases had a subnormal temperature. There was only 1 case of pneumonia with a subnormal temperature, and in that case the temperature had risen from 97·4° to 102° within three hours.

A low respiratory-pulse quotient combined with a high temperature is therefore far more typical of pulmonary disease than of abdominal. Of those cases of pneumonia in children where the pulse-respiratory quotient was over 3, the average temperature was 102·9°, the highest recorded being 105° and the lowest 101°. Of cases of pneumonia in adults with a respiratory-pulse quotient of over 3, the average temperature was 102·8°, the highest being 104·2°, and the lowest 100°. Of the cases of acute abdominal disease where the quotient was less than 3, the average temperature was 100°. The highest was 102° and the lowest 97°.

Pneumonia is not an uncommon complication of acute abdominal diseases, especially with cases of perforations of the stomach or duodenum, and it is interesting to note that with the onset of pneumonia the pulse-respiratory quotient falls and the temperature rises. Conversely, pneumonia may be complicated by suppurative peritonitis. Hector Mackenzie analysed 7868 cases of pneumonia and found that this complication occurred in 22 cases, 17 of which proved fatal. When the diagnosis of pneumonia is established the onset of abdominal symptoms should always arouse suspicion. The early recognition of general peritonitis and the prompt surgical relief may result in the patient's recovery, as it did in one of my cases.

The pulse.—The pulse of pneumonia is increased in rate, but does not usually become very rapid. In an average case, according to Wilson Fox, it is between 90 and 112. Grisolle found that in a quarter of his cases the pulse-rate was less than 100. In my series of cases the average pulse-rate of 31 cases occurring in children with lobar pneumonia was 131. Of these cases, 18 showed a pulse-rate of more than 120, and the highest recorded was 168. Of the 69 cases of lobar pneumonia occurring in adults, the average pulse-rate was 113·5. Eighteen of these cases (or 26·6 per cent.) had a pulse-rate of over 120. The highest pulse-rate recorded was 148, and the lowest was 80.

Comparing these averages with those of acute abdominal diseases the average pulse-rate of 27 children suffering from acute abdominal disease was 115, of which the highest registered was 140 and the lowest 82. Thus both the average pulse-rate and the highest recorded rate in children with acute abdominal disease are lower than in those suffering from pneumonia.

Among the adults the average pulse-rate of 206 cases of acute abdominal disease was 105. Of these cases 98 showed a pulse-rate of over 100—that is, 47 per cent. of cases, and 32 showed a pulse-rate of over 120, which is 16 per cent. of cases. This, I should think, is a low percentage for acute abdominal cases, but as compared with cases of pneumonia in the same series seems to show that the average pulse-rate of pneumonia is higher than that of acute abdominal disease.

Usually the pulse of pneumonia is full and soft for the first few days, but as a rule later becomes smaller and dicrotic. Irregularity is not often found, and James Mackenzie regards irregularity of the pulse in a case of pneumonia before the crisis as a very ominous sign. He has rarely seen a pneumonic adult with a pulse-rate of over 140 recover.

The blood pressure.—As a rule there is but little change in the blood pressure during the first few days, though it may fall 10 to 15 mm. of mercury (Wilson Fox). In severely toxic cases there may be a much greater fall. Where the pressure in millimetres of mercury is less than the pulse-rate the prognosis is grave. The blood pressure is very little affected in most cases of acute appendicitis, but in cases of acute general peritonitis, especially associated with perforated gastric ulcer, and in cases of acute hæmorrhagic pancreatitis the fall in blood pressure is great and rapid.

Cyanosis.—Unless the right side of the heart is failing cyanosis is not often seen with pneumonia (Pye-Smith and Beddard). Cyanosis is seen in severely toxic acute abdominal cases, but in these cases the cyanosis is also due to right-sided heart failure. Acute hæmorrhagic pancreatitis is the one acute abdominal condition frequently characterised by a cyanosis which increases in degree with the increase of the pulse-rate. This cyanosis is not a constant sign, but occurs sufficiently often as to be of diagnostic value. Many authors have drawn attention to this sign, especially Halsted and Moynihan. The cyanosis of acute pancreatitis is sometimes limited to the abdomen, and the face is ashy grey in colour.

Vomiting.—Musser and Norris found vomiting as an early symptom in 14 per cent. of 1328 cases of pneumonia, and as occurring some time during the illness in 27 per cent. of 5047 cases. Schapira found that vomiting was a common initial symptom, especially in children, as it occurred within 12 hours in 57 out of 173 cases of pneumonia which he collected. The vomiting associated with pneumonia is not as a rule persistent, such as is often the case where the peritoneum is involved, or in cases of intestinal obstruction. It may, however, be very persistent, and acute dilatation of the stomach is a well-known complication of pneumonia.

A case of pneumonia which terminated fatally is quoted by Anstie in which vomiting persisted not only during the pyrexial period but for 12 days afterwards, while the temperature remained subnormal. Such a case if associated with constipation may and has given rise to the mistaken diagnosis of intestinal obstruction.

Rigor.—This is a common prodrome of pneumonia. The frequency of occurrence and the intensity are greater in cases of pneumonia than in almost any other disease, with the exceptions of intermittent fever, pyæmia, and puerperal fever. Musser and Norris in an analysis of 9851 cases found it in 5731 cases, or 58 per cent. of cases. Huss observed rigors in 80 per cent. of his cases. Grisolle found it in 145 cases out of 182 cases, and of these it was the initial symptom in 101 cases. Louis found rigors as an initial symptom in 61 out of 79 cases of pneumonia. The rigor usually occurs at the onset, and is rarely repeated. Traube was of the opinion that repeated rigors should cause doubt as to the correctness of the diagnosis. Though occurring in cases of acute abdominal disease, it is not common, except in cases of acute suppuration of the gall-bladder or its associated ducts.

The skin and facies.—With pneumonia the skin is usually harsh and dry, and the cheeks are often flushed. It is not uncommon for one cheek alone to be flushed and that on the same side as the lung affected. In severe abdominal cases, especially where the general peritoneal cavity has been suddenly involved (such as in cases of acute perforation), the skin is often cold and moist. The cheeks are usually pale, and the expression of the patient is pinched and anxious.

Herpes.—This is a common complication of pneumonia. According to Geisler it occurs in 43 per cent. of cases of pneumonia. He analysed 421 of such cases, and found that it occurred in 182 cases. Of these 182 cases, in 1 case it appeared on the first day of the disease, in 18 on the second day, in 66 on the third day, in 41 on the fourth day, in 20 on the fifth and sixth days, and in the remaining 36 after the sixth day. That is to say, that of 421 cases of pneumonia 20 per cent. of cases developed herpes within the first three days of the illness. Riehl analysing 481 cases of pneumonia found that 179 cases developed herpes, 79 per cent. of which appeared between the third and fifth days. Although herpes seldom appears before the third day Aufrecht had a case where vesicles appeared two days before the pneumonia. In my series of acute abdominal diseases no cases of herpes were seen except in such cases as were complicated by pneumonia.

Bowels.—Irregularity of the bowels is not a common feature of pneumonia. McCrae states that in a series of 486 cases of pneumonia the bowels were regular in 57 per cent. of cases, constipation was present in 31 per cent. of cases, and diarrhœa in 12 per cent. of cases. Constipation, when present, may be very marked, and occasionally when such a case is also complicated with abdominal pain and vomiting, the diagnosis of intestinal obstruction is made. In acute cases of abdominal disease irregularity of the bowels is the rule rather than the exception, especially in cases of acute appendicitis, where constipation is more common than diarrhœa. In an analysis of 123 cases of acute appendicitis I found constipation in 81 cases, the bowels were regular in 30 cases, and diarrhœa was present in 12 cases.

Urine.—In cases of pneumonia the urine is usually diminished in quantity and increased in specific gravity. This increase in specific gravity may reach to 1035 when sugar is entirely absent (Lebert). Slight albuminuria is a more frequent complication of pneumonia than of almost any other acute disease. Thus, in a series of 67 cases analysed by Parkes albuminuria occurred in 30 cases. The excretion of chlorides is usually much diminished. Musser and Norris, analysing the statistics of Ashton, Landis, Musser, McCrae, Fyshe, Hadden, H. Mackenzie, and Ord, find that in some 450 cases the excretion of chlorides is normal in 19 per cent., diminished in 53 per cent., and absent in 28 per cent. of cases. According to Salkowski this hypochloruria is not merely the result of decreased consumption of salted food, but is a true retention of chlorides in the body. This hypochloruria is even found in those cases which are being given sodium chloride by the mouth (Beale).

In cases of acute abdominal diseases there is frequently diminished secretion of urine and increase of specific gravity, associated with the restricted fluid intake, vomiting, and fever, but albuminuria is rare except in very toxic cases. In such abdominal cases as involve the pelvic peritoneum pain on micturition, especially at the completion of the act, is a frequent and valuable sign.

Rectal examination.—Examination per rectum or per vaginam should never be neglected in doubtful cases, as by this method valuable knowledge of the condition of the pelvic peritoneum can be gained. Of all cases of pneumonia where this examination was made only one exhibited tenderness, which was on the same side as the lesion in the lung, but there was no swelling or bogginess to be felt.

B. *Pleurisy.*

Until the development of local signs of pleurisy the difficulty of excluding acute abdominal disease is greater than is the case with pneumonia. When local signs of friction or of collection of fluid can be found then the diagnosis is confirmed, but it is important to determine early whether the pleura or peritoneum is involved. The dry diaphragmatic pleurisy is most likely to give rise to the suspicion of acute abdominal disease. In such cases abdominal respiration is lost, and the rectus on the affected side may be as rigid as a board. Musser and Norris found abdominal pain in 5 out of 82 cases of primary fibrinous pleurisy, in 5 out of 374 cases of serofibrinous pleurisy, and in 2 out of 23 cases of primary purulent pleurisy—that is, 2·1 per cent. of 479 cases of pleurisy.

I may now briefly consider some of the signs and symptoms on lines similar to those already pursued in the discussion of pneumonia.

1. *The pulse-respiratory quotient.*—This is frequently lowered, but the perversion of the quotient is not nearly so striking as in cases of pneumonia. W. H. Walshe states that in a case of pure pleurisy he has never met with a lower quotient than 2·7. In one case of pleurisy which simulated appendicitis on admission the pulse was 136 and the respiration 52, a quotient of 2·6. On the next day the pulse was 112 and respirations 48, a quotient of 2·3.

That the perversion of the quotient is not as great as that of pneumonia is probably due to the fact that the cause of the dyspnœa is pain rather than toxæmia or pressure; indeed, it is remarkable how large a collection of fluid can accumulate *slowly* within the pleural cavity without increasing the respirations to any extent.

2. *The temperature.*—The onset of pleurisy is often marked by pyrexia, which may be considerable; indeed, Wilson Fox considers that *slight* pyrexia is the exception rather than the rule. The pyrexia is, however, usually of less degree than that of pneumonia. The average temperature of acute abdominal conditions has already been discussed, so I will only note that it is nearer that of a simple pleurisy than that of pneumonia.

The pulse.—The rate is usually increased, but is not as a rule very high, seldom being over 100 (Wilson Fox). Only a quarter of the cases collected by Woillez showed a pulse-rate of over 100, and in only 4 out of 182 cases of pleurisy did the pulse-rate range between 120–130. The case referred to is therefore exceptional in presenting a pulse-rate of 136. Referring to the statistics of my series of acute abdominal cases when comparing the average pulse-rate with that of cases of pneumonia, among adults 47 per cent. of cases showed a pulse-rate of over 100, which is twice the percentage that Woillez found in his series of cases of pleurisy.

Vomiting.—This is not uncommon in cases of pleurisy occurring among adults, but according to Barthez and Rilliet it occurs during the invasion in over 50 per cent. of cases among children. As in cases of pneumonia, the vomiting is neither so persistent nor severe as that associated with acute abdominal disease.

Rigor.—The onset of pleurisy is frequently accompanied by a rigor, but the rigor occurs less frequently, and is less severe or protracted than that associated with pneumonia. I have already discussed the occurrence of rigor in acute abdominal disease.

C. *Pericarditis.*

With regard to the differential diagnosis between pericarditis and acute abdominal diseases, great difficulty may be experienced, as is evidenced by the fact that 3 out of 4 cases of pericarditis admitted as cases of appendicitis underwent laparotomy. The difficulty is increased by the fact that in such cases of this nature as I have analysed the abdominal symptoms preceded the development of physical signs of pericarditis by many days. On what signs, therefore, is an early differential diagnosis to be made?

The history.—A previous history of pains in joints, limbs, or of a sore-throat should always arouse suspicion that the alleged case of appendicitis may really be a case of pain referred to the region of the appendix. I have not yet seen a case of uncomplicated acute abdominal disease where the onset was marked by pains in joints or limbs.

The pulse-respiratory quotient.—This is of little assistance as it is not generally low, but is similar to that associated with acute appendicitis and other abdominal conditions. The temperature also is of little help, as a moderate pyrexia is the rule rather than the exception.

Summary of the Average Pulse, Respiration, and Temperature of 30 Cases of Acute Pericarditis in the Early Stage.

Adult males.—Number of cases, 12. Average temperature, 100°. Pulse, 114. Respirations, 27·2. Quotient, 4·2.

Adult females.—Number of cases, 11. Average temperature, 100°. Pulse, 109. Respirations, 28·3. Quotient, 3·8.

Total adult cases.—Number of cases, 23. Average temperature, 100°. Pulse, 110·8. Respirations, 27·8. Quotient, 4.

Children.—Number of cases, 7. Average temperature, 99·7°. Pulse, 114. Respirations, 30. Quotient, 3·8.

Among adults the lowest quotient was 2·8, and the highest temperature 102°. Among children the lowest quotient was 2·6, and the highest temperature 101·2°.

Vomiting.—This condition is sometimes associated with pericarditis and may be very persistent. James Mackenzie, however, states that he has "never seen vomiting arise as a reflex in heart affections, nor, for that matter, from a lung affection."

The condition of the abdomen.—In those cases of pericarditis which closely simulate abdominal crises cessation of abdominal respiration is common, with associated rigidity of the recti and tenderness. In many cases, however, of pericarditis there is reversed abdominal respiration—that is to say, that the abdomen sinks on inspiration. This is due to paralysis of the diaphragm. Wynter states that "though in the majority of thoracic cases affecting the lung and pleura this is one-sided, and the influence on abdominal movement is proportionately less marked, in acute pericarditis the cessation of phrenic action is bilateral, and consequently absence of abdominal movement is as obvious as in abdominal disorders, though rigidity and general tenderness are for the most part lacking." He further states that in two years he has met with 30 cases of pericarditis in which loss of abdominal respiratory movement led to the detection of pericarditis—a number so much in excess of those usually noted that it at once demonstrates the value of such a sign in assisting to recognise a very obscure condition, and suggests that numbers of instances of pericarditis have hitherto been overlooked.

In the analysis of 30 cases of pericarditis the result was: Among adults the local signs were preceded by cessation or diminution of abdominal respiration in 20 out of 23 cases. Abdominal pain and tenderness were noted in 4 of these cases. Among children local signs were preceded by alteration of abdominal respiration in 4 out of 7 cases, and one of these cases experienced abdominal pain and tenderness.

The Acute Abdominal Conditions which may be Simulated.

Acute intrathoracic disease may simulate practically any acute abdominal condition. I will briefly mention such conditions which I have found among my cases and literature. Pneumonia can simulate (1) perforated gastric ulcer; (2) appendicitis; (3) cholecystitis; (4) gastro-enteritis; (5) hæmorrhagic pancreatitis, as in the case quoted by Sir William Osler, on which Halsted performed laparotomy; and (6) intestinal obstruction. Pleurisy is most likely to simulate acute appendicitis when the right pleura is involved. Pericarditis may simulate: (1) Appendicitis; (2) perforated gastric ulcer; (3) acute hæmorrhagic pancreatitis; and (4) duodenal ulcer.

I may now mention some signs which are found associated with these various abdominal conditions, and which if found would confirm the diagnosis.

1. *Perforated gastric ulcer.*—Signs of free gas in the peritoneum. If found, this is a positive sign of perforation of a hollow viscus. Great care must be taken to be certain that the gas is free, as mere diminution of liver dulness may be due to a distended stomach or colon. Absence of this sign does not exclude the diagnosis of perforated gastric ulcer. There are other points in the history, the condition of the patient, &c., which have been already mentioned, but which are inconclusive.

2. *Acute appendicitis.*—A definite swelling in the right iliac fossa, especially if this swelling is confirmed on rectal examination, will render the diagnosis likely to be accurate. A cæcum distended by fæces may prove misleading.

3. *Acute cholecystitis.*—If the presence of a large tender gall-bladder can be determined then there will be little doubt as to the diagnosis, but it is not always easy to demonstrate this when the abdominal wall is rigid and when hyperæsthesia exists.

4. *Hæmorrhagic pancreatitis.*—The acute onset of great epigastric pain associated with extreme collapse, cyanosis of the abdomen and perhaps of the face, if occurring in a stout and middle-aged patient, should arouse suspicion as to the possibility of the pancreas being at fault. The only sign which will render the diagnosis almost certain is a swelling in the region of the pancreas, which may present between the stomach and the transverse colon, below the colon or above the stomach. It is usually impossible to find this, even when present, owing to the exquisite tenderness of the upper part of the abdomen and the rigidity of the muscles.

5. *Acute intestinal obstruction.*—Constipation, if absolute (that is to say, if neither flatus nor fæces are passed after the use of enemata), is certainly never due to intrathoracic disease. The commonest cause of *acute* intestinal obstruction in an adult is strangulation of a hernia. Thus in 1912 the total number of cases of acute intestinal obstruction (including intussusception) admitted into three metropolitan hospitals was 193, of which 122 cases were of strangulated hernia. In cases of suspected obstruction the hernial orifices (normal and abnormal) should be examined, as frequently the patient is unaware of the fact that he is ruptured until the hernia becomes strangulated, and is thus discovered.

One condition which, as mentioned earlier in this thesis, sometimes complicates pneumonia and resembles intestinal obstruction in the abdominal distension is acute dilatation of the stomach. Of 44 cases of acute dilatation of the stomach collected by Campbell Thomson 3 cases occurred as a complication of pneumonia. When this complication ensues constipation is not absolute, and the abdominal distension can be shown to be limited to the stomach. Moreover, immediate relief can be given by lavage of the stomach, although recurrence of the condition is not unlikely to ensue.

Conclusions.

Severe abdominal pain, often accompanied by vomiting, rigidity of the muscles, and even localised tenderness, may exist without any lesion of an abdominal viscus. When possible it is advisable, therefore, to examine the thoracic viscera before submitting a patient to laparotomy. A thorough examination is frequently impossible owing to the condition of the patient, but in all cases the pulse-respiratory quotient can be analysed and considered with the temperature. I consider this quotient to be of the utmost value, and if attention be paid to it I do not think many cases of pneumonia will be treated by abdominal section. With regard to pleurisy and pericarditis, reliance cannot be placed on either the quotient or the temperature, and as in the past so in the future will mistakes occasionally occur. In all very acute abdominal cases, where the general peritoneal cavity is involved, tenderness is usually elicited on rectal examination and actual swelling is often found; a rectal examination should therefore be made in all suspected acute abdominal conditions. In doubtful cases the history of the onset should be considered, as pericarditis is usually preceded by tonsillitis or pains in one or more joints.

The treatment of cases where doubt exists as to the diagnosis.—When the abdominal signs are so serious that one concludes that if the disease is abdominal the condition is so severe that surgical procedure offers the only hope, then I believe that laparotomy should be performed. Against this view is the fact that if the case is due to pneumonia then harm must be done to the patient by the operation, for apart from shock, the inhalation of ether must have a prejudicial effect on the already congested lungs, and chloroform must still further embarrass a heart enfeebled by toxæmia. In a case presenting such a dilemma the safest procedure would be to perform the operation under local anæsthesia. I have seen this method adopted in the case of a child suffering from lobar pneumonia and general peritonitis. The child stood the operation well, though the disease subsequently proved fatal.

In my series of cases of pneumonia only one underwent laparotomy under a general anæsthetic. The anæsthesia was induced by chloroform and maintained by open ether. The patient died four days after the operation. In Richardson's series of cases one case, a boy aged 6, was treated by laparotomy on the fifth day of the illness. There is no note of the anæsthetic used. The pneumonia was unilateral. This patient recovered. Of Barnard's cases one, a girl aged 17, underwent laparotomy on the second day of the disease. The anæsthetic used was ether. The pneumonia was bilateral, and the patient died on the fifth day of the disease. Therefore, of the 3 pneumonic patients on whom laparotomy was performed, 2 died and 1 recovered. To what extent the operation contributed to a fatal result it is impossible to say, but both were severe cases, and both survived operation for four days, dying on the fifth day of the disease. Musser and Norris state that the fifth, sixth, seventh, and eighth days of disease show the highest mortality.

Acute general peritonitis due to a perforated viscus or a gangrenous appendix, if untreated by the surgeon, almost invariably causes the death of the patient. "Excluding the favourable influence of operative interference, it may be said that no case of diffuse peritonitis due to perforation can be expected to recover spontaneously" (Allchin). Laparotomy does not seem to prejudice the chances of the patient's recovery in cases of pleurisy or pericarditis, as of the five cases I have collected the patients all recovered. Though in each of these cases an error of judgment had occurred, the error lay in the diagnosis rather than in the treatment, for if the diagnosis had been correct surgical interference was the correct treatment, and I consider that under the circumstances the best was done for the patient's good. In all cases the diagnosis is the difficulty; the treatment depends on the diagnosis. In all serious cases where, though there is doubt whether the thorax or the abdomen is at fault, the latter is considered as the probable site of disease, then I think it is to the patient's interest to decide the diagnosis by laparotomy rather than to risk making the diagnosis on the post-mortem table.

SOME OBSERVATIONS ON 376 CASES OF "FROST-BITE."

BY CHARLES MILLER, M.D. CANTAB.,
M.R.C.P. LOND.,
ASSISTANT PHYSICIAN, LONDON HOSPITAL; MAJOR (TEMPORARY), R.A.M.C.

Three hundred and seventy-six soldiers have been admitted to the British Red Cross Hospital, Netley, suffering from so-called "frost-bite." 100 consecutive cases were examined and certain questions were asked of each man. The following particulars have been compiled from their answers. 1. It was freezing at the time of the "frost-bite" in 65 out of 100 cases. 2. Every man was wearing short boots with more than one pair of socks. The majority were wearing puttees. 3. Change of colour in the feet, red-blue, blue, or black, was noticed by the patient in 58 per cent. of the cases. Among these men it had been freezing in 40 cases. 4. In the remaining 42 per cent. the feet were said to be pale. Among these men it had been freezing in 25 cases. 5. In the 58 "coloured" cases the first symptom was numbness or "dead feeling" in 37, pain in 14, and painful swelling in 7. 6. In the 42 "pale" cases the first symptom was numbness in 23, pain in 9, and swelling in 10. 7. In all cases the men had been standing in mud or mud and water of a depth varying from 18 inches to 3½ feet for many hours.

It is difficult in many cases to be certain which is the first symptom, for when a patient arrives at a base hospital some days have already elapsed since he reported sick, and he has to rely upon his memory. But in both "purple" and "pale" cases numbness and "dead feeling" are given in a large majority of cases as the first symptom.

It is clear that it is not necessary for the temperature to be below freezing-point for the production of "frost-bite." Further, there is an almost equal proportion of "purple" and "pale" cases in which it was not freezing. It would seem that the "pale" and purple cases are produced by the same factors, and may be regarded as different varieties of the same condition; and it may be noted that in a few cases one foot was pale and the other discoloured, though it is usual for both feet to be similarly affected.

Physical Examination.

1. *General.*—The appearance of the feet differs in many respects. As already said, the feet may be "pale" or "purple." Further, in some of the "purple" feet there may be blisters containing dark and usually offensive fluid and ulceration of varying depth. The "pale" feet are of a creamy-white colour, and the skin is dry and inelastic. The foot radiates heat to a distance of two or three inches, the radiation being easily perceptible by the hand. These feet have been said by some observers to present no abnormal appearance, but the characteristic colour and the radiation of heat are definite variations from the normal. Further, the subjective symptoms of pain and tingling are most prominent symptoms in the "pale" feet, with the result that the patient becomes a nervous wreck from want of sleep. In the "purple" feet the discolouration is usually deep purple; it is most evident on the ball of the great toe and at the bases of the other toes. The discoloured area is anæsthetic, but at its margins sensation may be acute. Blisters are most common on the dorsal surface of the toes and foot. Ulceration may follow the blisters or occur independently, and may affect the skin and subcutaneous tissues only, or go down to bone. In the "purple" feet the subjective symptoms are not so severe as in the "pale" feet.

2. *Nervous changes.*—(*a*) Normal sensation was never present in the whole of a "frost-bitten" foot.

(*b*) Anæsthesia was present in many cases. In some the toes only were anæsthetic, a phenomenon most evident in toes that were becoming mummified. In these cases the dorsum of the foot was often very tender. In other cases there was anæsthesia of a sock or stocking area. In several of these cases it was possible to show that there was a larger area of anæsthesia for light touch than for pin-prick. In others it was not possible to get satisfactory answers. In a few cases there was definite anæsthesia of a peripheral type over the region of a particular nerve. The external cutaneous and the peroneal nerves are examples.

(*c*) Hyperæsthesia was present in very many cases either by itself or in a foot which was partly anæsthetic. It was impossible to make out any anatomical distribution of hyperæsthesia, but its severity was remarkable. Such stimuli as cotton-wool and a current of air would be resented by the patient in the most severe cases. Such cases were invariably of the "pale" variety.

(*d*) *Motor changes.*—The individual toes could not be moved or could be moved only with difficulty. The great toe in the majority of cases was held in the position of dorsiflexion.

Treatment.

General.—The chief objects of treatment were to relieve the pain and to secure sleep. Various drugs have been tried—e.g., aspirin, phenacetin, trional, &c. But they were found uncertain in their action, and the most severe cases were given a hypodermic injection of morphia. Many of these patients felt thoroughly ill from the effects of exhaustion and exposure and required good nursing, good food, and plenty of sleep. They seem particularly open to attack by the organisms of influenza and enteric fever.

Local.—1. *Warmth* was useful in a few cases only. If the feet are anæsthetic warmth apparently does good, and again when the feet are nearly well. Bed-socks, cotton-wool covers, or hot bottles will supply sufficient warmth. Radiant heat from electric lamps was tried with good results in a few cases.

2. *Cold* is necessary in the majority of cases. The atmospheric air at this time of the year is cool enough to be soothing to the patient. The usual plan was to leave the feet uncovered and guarded by a bed-cradle. A sheet could be placed over the cradle to cut off draughts.

3. *Position.*—The feet were more comfortable if raised on pillows, and by this means any œdema would be made to disappear.

4. *Massage* was beneficial in the majority of cases. At first it has to be very light, but later more vigorous massage with passive movements was tried. The massage can be dry or with some lubricant.

5. *Applications.*—Various oils were tried with equally good results—e.g., eucalyptus oil, methyl salicylate oil, and a mixture of castor oil, glycerine, and atropine. In the cases of blisters and ulceration dry dressing was employed, some powder such as boric acid or one of the bismuth compounds being used.

Results.

The results have been good, but there is no guide as to the duration of symptoms. It is the custom to send the patient on furlough when he can walk comfortably in boots. Œdema of the feet after walking takes a long time to disappear.

Complications.

Tetanus has occurred in two cases of ulcerated "frost-bite." Both patients have survived. Dry gangrene of toes or part of the foot was fairly common. The dead tissue separated after a line of demarcation had been formed. Sometimes superficial tissues only are affected, and a granulating surface is left. Wet gangrene occurred in one patient, an Indian; amputation was necessary in this case. Thrombosis of the saphenous vein, with a high temperature and rigors, occurred in one case. It is worthy of note that seven patients who had been in hospital in France for a week with "frost-bite" developed enteric fever a few days after their arrival at this hospital. Many have been victims of the "influenza" epidemic.

Causation.

The causation is necessarily a matter for speculation. Certain factors are doubtless of importance. The lowered temperature, not necessarily to freezing-point, is probably of great importance, but in my opinion the immobility of the feet and legs is even more important. The feet are cramped in boots that are made too tight by the extra socks worn; the legs may be kept stiff by badly applied puttees, and the whole limb is held motionless by the inertia of the mud and water of the trenches. The combination of the two factors, cold and immobility, will destroy the vitality of all the tissues of the part — nerves, blood-vessels, lymphatics, muscles, and skin. The lessened vitality will cause loss of function in these tissues, with venous stasis, impaired nerve conduction, and disordered vaso-motor functions.

Prevention would necessarily be difficult. If a soldier in the trenches wore large waterproof boots in which he could move his toes and leg muscles he might escape "frost-bite," but his activity would be impaired.

In conclusion, I wish to express my opinion that it is incorrect to regard one group of these cases as "neurotic" or "functional." From the cases I have seen I must believe that there is no difference between the forms of so-called "frost-bite" as regards causation. The differences are in the effects on different individuals, and they are merely different manifestations of the same condition. The definite physical characteristics of these "pale" feet which have been diagnosed as "functional" by certain observers are not such as are found in "functional" disorders. It can be admitted that these patients are in a condition of nervous exhaustion, but their previous hardships, to which are added pain and loss of sleep from pain, are sufficient causes for their appearance. Further, the different effects of "frost-bite" may be seen in the same individual and even in the same foot. Whatever else may be discovered about this condition, I personally am satisfied that it is primarily physical and only secondarily psychical.

British Red Cross Hospital, Netley.

A NOTE ON "FROST-BITE."

By F. McG. LOUGHNANE, F.R.C.S. Eng.,
RESIDENT SURGICAL OFFICER, SALFORD ROYAL HOSPITAL; LATE BRITISH RED CROSS SURGEON, MEERUT STATIONARY HOSPITAL, BOULOGNE.

"FROST-BITE," so called, as it has affected the health of the troops in France, is not only of extreme military importance, but is also interesting from the point of view of treatment, preventive and curative. Out of 160 patients admitted to hospital one evening about 120 were cases of frost-bite alone, and many of them were stretcher cases. These were very bad cases in which both feet were affected, and so painful and tender that no walking could be attempted, even with the aid of a stick. This is the largest proportion I have seen admitted to hospital in any one day for over two months, but fortunately, although some were so serious as to be incapacitated completely for the time being, they would for the most part recover, unlike many of those previously admitted, for whom amputation was often necessary.

Causation.

There seemed to be no selective racial incidence of the disease. Hill men, such as the Gurkhas, suffered equally with the Sikhs and those from warmer parts of India. Indeed, so far as I could gather from the other hospitals in Boulogne, the Indian troops withstood the rigours of a winter in Northern France no worse than did the European soldiers.

A low degree of temperature is the primary etiological factor in classical frost-bite. This, however, was not the chief determinant in France, where the cold at the time was not very severe, although generally the weather conditions were extremely bad. The feet alone suffered. I failed to see any case amongst the Indians of chilblains or chapped hands. The condition of the feet was brought about by the accumulation of contributory causes, all tending to produce in greater or lesser degree circulatory stasis. These were cold, wet, fatigue, the wearing of tight boots and puttees, and prolonged standing, conditions difficult to preclude in trench warfare in winter time, when soldiers have to stand for many hours over ankle-deep in mud and slush. In regard to boots a vicious circle develops. The wet leather shrinks and presses on the feet, thereby setting up traumatic inflammation and swelling, which swelling in turn increases the pressure from the boots. I think that in most cases ill-fitting and too-tight boots are direct predisposing causes, though these are aggravated and brought into play by constant cold and wet. "Boot-bite" and not frost-bite might be a more correct term. The number of cases showing definite pressure lesions in places usually caused by boots—viz., the prominences of the toes, the inner side of the hallux and heel—was very great. In many of the cases a considerable degree of septic infection was manifest, which is not surprising considering the general lack of care which was often taken in regard to personal hygiene. In fact, it was this seriousness of infection which chiefly determined the gravity of the case.

Symptoms.

Though not easy to ascertain the exact pathological conditions present in frost-bite, few amputations being performed in the early stages, unless serious sepsis or moist gangrene supervenes, yet on the whole the impression one gathers is that of a low-grade inflammation, secondary to vascular changes, affecting not only the skin and superficial tissues, but also the deeper structures, such as muscles, tendons, joints, and bones. Many of the patients complained of pain in the bones and muscles long after all other signs and symptoms had disappeared. I had to amputate in two cases only. In one septic moist gangrene had developed in one foot, and in the other case emphysematous gangrene. When, naked-eye, the parts were examined after amputation, there was found to be an excess of fluid in the cellular tissues, tendon sheaths, and ankle-joint. The subcutaneous fat was yellower than usual, the muscles pale and flabby, and many patches of subcutaneous hæmorrhage were scattered about. The skin in places was obviously necrosed, and often the necrosis extended down to the tendon sheaths. The epidermis was soft and succulent, and could easily be rubbed off.

Clinically many different types of these frost-bitten feet may be recognised, according to the stage at which they are first seen, but in a broad classification may be arranged as follows:—(1) Pain; (2) swelling; and (3) gangrene. This is in accordance with the predominating sign or symptom. The number of cases with pain alone, however, were remarkably few. As a rule pain and swelling were both present. Of the varieties of gangrene—dry, moist, local, and spreading—the commonest obtaining was a dry, local gangrene. Dry gangrene was sometimes associated with swelling, but as often without.

In general appearance the feet showed marked variation. Some were extremely swollen and œdematous, with tense, shiny skins. In others there was little if any swelling, but in patches the skin was blanched and crinkled or stretched. When much swelling was present careful inspection revealed increased vascularity of the skin, which could be rendered much more evident, however, by using gentle pressure with the finger, thus effacing the superficial circulation, and noting the different effect from that produced thereby in a normal area of skin elsewhere. The redness of inflammation was always difficult to detect in the Indian skin by inspection alone.

The skin was generally of a dark, purple-blue colour, more intense on the dorsum than on the sole, which, except in very pronounced cases, seldom showed any marked change. Peripherally this dark colour shaded insensibly into the normal dark colour of the skin. In the average case a definite colour line of demarcation was seldom seen. Blebs frequently formed on the dorsum of the foot. They were subcuticular and often multilocular. Usually more than one were present. They contained dark, blood-stained fluid; seldom pus even when elsewhere the foot was obviously infected. The skin on the prominences of the toes might be dry and shrivelled and quite hard. On the inner side of the big toe and heel a circumscribed, dry, gangrenous patch was not frequently the only lesion, unaccompanied by general swelling of the foot. The appearance was that of a large dry scab which took some time to slough off, leaving, when it did, a raw granulating surface which healed slowly. In some cases the swelling and œdema were very marked, and involved not only the foot but extended up the leg to the knee. The swelling was most tense over the foot, which was very painful, especially when the plantar fascia was stretched. Pitting on pressure was not characteristic of the œdema; it occurred principally on the leg.

Pain and numbness were the chief symptoms complained of. The former was never very severe, and seldom required alleviation by drugs. Generally local, it was occasionally of a neuritic type, shooting up the leg to the knee, and in one case even as far as the hip. The pain was tingling, pricking, and very persistent, being present for a long time after all signs had disappeared. Occasionally, when the feet were numb, a neuritic pain extended from the feet upwards. No anatomical nerve area was affected, sensory changes being either diffuse over the whole foot or occurring in patches. The calf muscles at times were very painful.

To touch the skin of the feet seldom felt cold, and not infrequently the only sign of lowered vitality was irresilience of the tissues. A diminished elasticity could be demonstrated in almost every case, and was a constant precursor of gangrene. It was always present beyond the edge of a definitely gangrenous patch.

Tenderness was a well-recognised feature. Gentle palpation could generally be carried out with comparative ease, but anything resembling rough handling or firm pressure was sincerely resented. It was a deep tenderness involving muscles and tendons rather than the skin and subcutaneous tissues. If the feet were at all bad the muscles of the calf were in most cases extremely tender. This tenderness had little relation to pain and swelling; it was present when these were absent, and was most marked when all three were present.

Many of the cases ran a temperature from 99° to 100° F. These latter were bad cases of sepsis and emphysematous gangrene, and fortunately were comparatively few. In these cases the odour from the feet was most offensive, and the patients showed marked signs of toxæmia. Very seldom were both feet equally bad, though some of the cases sent to England looked as though they might require amputations at a later date—probably a Syme on one foot and a Lisfranc on the other.

Two Cases of Amputation.

Early amputation was never resorted to unless rendered urgent by the extreme toxic condition of the patient, and fear of spreading infection. The way doubtful cases cleared up under treatment was astonishing; and it was very gratifying to see how cases which on admission seemed so hopeless as to make conservative treatment appear futile, recover to such an extent that the resulting deformity consisted merely in the loss of a toe or toes. In the two following cases, however, prompt radical treatment became necessary early.

CASE 1. *Bilateral frost-bite.*—Patient had been engaged in digging trenches, but did not sleep nor stand about in them. There was no frost at the time. After five days the feet became painful and swollen, and he was treated at a front hospital for a week when, no improvement having taken place, he was sent down to the base. The right foot was a livid, purplish blue, very swollen and œdematous, with blebs on the dorsum. The œdema extended up the leg, pitted on pressure, and gave a slight crackling sensation on palpation. The leg was very painful. Temperature 102° F. The foot was powdered, swathed in a voluminous dressing of cotton-wool, and raised on pillows. The œdema of the leg subsided, no further crackling could be obtained, but the stench from the foot was much more overpowering, and the temperature rose to 103°. A week after admission I performed a Farabœuf's amputation below the knee, and left in a wide drainage-tube. Two days later, as the temperature had not fallen, and a few bubbles of gas appeared in the wound, I removed all the stitches and treated the stump as an open wound with hydrogen peroxide 10 volumes and carbolic acid 1 in 40. Next day the temperature fell to 100°, and by the end of a week the stump was clean and healing. The patient's general condition, very bad before the operation, improved rapidly as a result of the amputation. The left foot had only dry gangrene of the toes and anterior tarsus.

CASE 2. *Bilateral gangrene.*—Left foot was dry with only the toes affected. The right was moist and stinking. Œdema not very marked. Temperature 102° F. A line of demarcation had formed above the ankle. I performed a Farabœuf's amputation below the knee, and the stump healed well by first intention.

General Remarks on Treatment.

The subject of treatment is a wide one, and will be considered in its three phases—preventive, active, and convalescent. As in the case of a good many other complaints, preventive treatment is the most difficult to carry out. There is little doubt that if the men were able to observe the rules of ordinary cleanliness and to change their wet boots and shoes regularly few cases of frost-bite would be recorded. Necessarily recourse must be had to other means. Some of these, however good in theory and at other times, are fanciful and impracticable in an emergency. I discussed this with a traveller whom I met in Boulogne, who had had considerable winter experience for many years in North-West Canada. I was informed that there, amongst seasoned travellers and backwoodsmen, a case of frost-bite hardly ever occurred, no matter how cold and wet the weather; and he suggested that it might well repay the Government to include in the army some North-West Canadians, whose sole duty it would be to attend to the welfare of the soldiers' feet. He recommended that several pairs of moccasins should be worn over one or two pairs of thick woollen stockings. The moccasins, made of skin, are light, watertight, and roomy. They will withstand any amount of hard wear on soft, wet ground, and would be admirably adapted for use in the mud and slush of the trenches. The outer pair or pairs could be removed and dried when the occasion offered; the innermost pair never become wet. Moccasins, however, could not be used for marching purposes, as they wear out on hard ground, and the manner of walking in moccasins is quite different from that in boots. Moreover, this scheme is impracticable, for neither, when the need is urgent, could the requisite number be obtained in the desired time nor the troops taught how to use them properly. The wholesale adoption of rubber boots, which would be equally beneficial, is also impracticable. A remedy exists, however, in improving the foot-gear commonly employed. The boots worn are too small, ill-shapen, and the leather of the uppers too hard and unyielding. The boots need to be at least two sizes too large to allow for the comfortable wearing of two pairs of socks and the swelling of the feet which prolonged standing is apt to entail. Moreover, boots shrink at least one in size when constantly wet and soaked in water. I hardly ever saw an Indian patient with comfortably fitting, roomy boots. They could seldom be laced up properly and frequently would only fit in the absence of socks. I saw many cases come into hospital with the heel-part of the uppers crushed down and only the anterior part of the foot in the boot. There was no room for the whole foot.

In the active stage treatment will necessarily vary considerably according to the condition present. The milder cases, showing little, if any, organic change, but much incapacitation from pain and tenderness, should, like the more serious ones, be given absolute rest in bed. The feet should be well powdered, and covered with a voluminous dressing of cotton-wool. Too often patients were admitted with a scrappy little dressing inadequately bandaged on. The wool should be four or five layers deep, loosely and thoroughly envelop the whole foot, and extend well up the leg beyond the area of pain and tenderness. The bandage should be very lightly applied, yet firm enough to retain the dressing in its place. Thermogen wool, if available, is the best to use, for it possesses greater heating properties than the ordinary unmedicated wool, but being more expensive it is limited in general use. The dressing need not be changed frequently, but may be left on for four or five days. When pain and tenderness are no longer acute, much benefit may be derived from gentle massage and exercise. Massage, generally with oil, had a decided influence in the relief of pain; and in conjunction with movements—active and passive—in shortening the period of convalescence. At first massage should be confined to light, gentle stroking, becoming brisker as the condition of the feet improves, until ultimately resembling the vigorous rubbing of the popular, homely masseur. Movements of the different muscles and joints were carried out at first in bed, at frequent intervals throughout the day, but as soon as the patient's state allowed he was put on discontinuous walking and tip-toe exercises, resting in bed in between time. Hot-water bottles and fire have to be avoided as a means of improving the circulation, warmth can always be obtained by cotton wool and friction. Apart from the danger in exciting a general gangrene when frost-bitten feet are placed too near the fire, due to a sudden increase of fluid in the tissues consequent on a too rapid thawing, seeing that sensation in many of the cases is numb or absent, a serious burn might easily be inflicted. This was ever to be guarded against at the Indian Hospital, for when left to themselves the patients were apt to get out of bed and squat on the floor, with their feet resting against the stove in the centre of the ward.

In the presence of broken skin or the feet assuming a moist condition, after a preliminary painting of the skin with tincture of iodine 3 per cent. in methylated spirit, the limbs, well covered with cyanide gauze and cotton-wool, were raised on pillows three or four deep. This was preferable to slinging them from a cradle, for not only was more support thereby given, but the patients complained much less of pain. No matter how well the limb was padded, complaint was invariably made of pain at the level of the sling, and the œdema took a much longer time to subside. Often the painting with iodine was repeated, and this process, in addition to alleviating pain, acted as an antiseptic and dehydrant.

In consequence of this treatment a large majority of the cases which were on the borderland between dry and moist gangrene ultimately settled down and became resolved into the former and much more hopeful variety. The dusting powder I employed was a mixture of starch powder, zinc oxide, and boric acid in equal proportions. The mixture is dehydrating, stimulating, and antiseptic. Moist antiseptics and fomentations are not to be recommended, even if the case is septic.

Amputation should be postponed to the last, but never delayed unduly at the risk of the patient's life. I have seen one death follow a too strict adherence to conservative treatment. So long as the patient is suffering but little from the effects of toxic absorption, and pulse-rate and temperature are satisfactory, the iodine and powder treatment ought to be persevered with. When patients are first received into hospital from the front they seem to be in a much worse condition than reality justifies; their vitality is sapped by exposure in the trenches and the hardships of transport by train and ambulance. Some of them had been without food for two or three days, and arrived at their journey's end constitutional wrecks, broken down mentally and physically. It will hence easily be understood how many of the cases, with foul-smelling and swollen feet, discoloured, gangrenous, and septic, convey at first the impression that the condition is an extremely grave one, and that life is in imminent danger of dissolution unless prompt radical treatment is instituted. After a few days of hospital comforts, however, with rest, warmth, and food in plenty, improvement in general health is rapid, and concurrently the local lesions assume a much healthier and less morbid appearance. When amputation was the only choice the leg was removed below the knee. Other cases, showing ingravescence of the gangrenous area, were removed to England.

Treatment in the early days of convalescence is similar to that adopted in the milder cases. The essentials are massage and exercise, with rigorous avoidance of cold, wet, and fatigue. It may be commenced with as soon as the patient will allow it, when pain and swelling have somewhat abated. The most difficult symptom to overcome is pain, which outlasts the swelling for a considerable time and is often of a recurrent character, disappearing altogether for a day or week, then returning with crippling intensity with a change in the weather or the continuance of work, thus in a way resembling chronic rheumatism. When this occurs confinement to bed again becomes necessary. Drugs confer only temporary relief. Frequently one of a fatigue party from among the convalescents had to be readmitted to hospital for painful, occasionally for swollen feet. This was not a mere plea to escape work, for often as not it was a Gurkha who was thus disabled, a man who was always willing to help and seldom a shirker. The sooner a patient is put on exercises, at first in the ward and then as one of a fatigue party, the better. Too protracted a stay in bed or hospital renders the feet very sensitive. A return to the normal condition is best brought about by encouraging a normal circulation which will follow on the physiological use of the parts concerned.

SECTION OF OBSTETRICS.

Unusual Degeneration of the Cervix.—The "Dublin Method" for the Third Stage of Labour.—The Alexander-Adams Operation.

A MEETING of this section took place on March 12th, Dr. M. J. GIBSON, the President, being in the chair.

Dr. ALFRED SMITH showed a case of an Unusual Degeneration of the Cervix in a patient, aged 60, the mother of 16 children, who consulted him for a profuse slimy discharge. The menopause came on ten years ago. She had enjoyed good health up to August last, when she noticed a slimy discharge from her vagina, without hæmorrhage, pain, or offensive odour. On bimanual examination the vaginal portion seemed to have disappeared, the margins being flush with the vaginal vault, the os being so dilated as to admit the index and middle fingers. There seemed to be no internal os; the cavity of the uterus was greatly dilated; the mucous membrane felt like velvet pile. This slight palpation caused hæmorrhage. On curettage, quantities of brain-like matter reported non-malignant came away, as in cancer. Simple panhysterectomy was performed. The total length of the uterus was 12 cm., fundus 3·5 cm., cervix 8·5 cm., greatest width 6·7 cm. The fundus was normal, but the cervical portion was greatly thickened, due to the transformation of the normal muscle wall into a spongy mass infiltrated with mucoid material, directly continuous with much mucus in the cavity of the cervix. The whole contour of the cervix was affected, more markedly in the anterior and left wall. The true cervical wall was represented by a thin layer of fibro-muscular tissue. No evidence of malignancy. The specimen was in the nature of a channelled mucous polypus, but was remarkable in that it engaged more or less uniformly the whole of the cervical wall.—Dr. E. HASTINGS TWEEDY said it seemed to be an adenomatous condition of the mucous membrane, something like a mucous polypus, spreading over the entire surface.—Dr. R. J. ROWLETTE said he had never seen anything like this exhibit. It possessed remarkable similarities to the glandular structure found in mucous polypi. Why a tumour should sometimes be so confined and at another time so diffuse as this was a problem.

Dr. T. P. C. KIRKPATRICK investigated the claim put forward that the method of conducting the third stage of labour, known for so long as the "Dublin method," had originated in Dublin. He showed by extracts from the "Midwifery" of Fielding Ould, published in Dublin in 1742, that this method was not then taught by him. After Ould, the next work on midwifery by a Dublin writer was that published by Foster in 1781; yet even in this work the "Dublin method" was not clearly described. In 1768, however, John Harvie had published in London a short pamphlet in which he gave a clear and exact description of the method. It seemed probable, then, that Harvie was the first to describe the method, and that subsequently it was adopted as the teaching of the Dublin Lying-in Hospital. Though the Dublin school might not be able to claim the honour of having first described the method, yet that school deserved credit for so early recognising its value and for so consistently teaching it.—Dr. R. D. PUREFOY said he thought the idea of robbing the Rotunda Hospital of the credit of producing a practice which obstetricians all the world over admitted was a markedly safe one might have been left to someone else. That Dr. Kirkpatrick had succeeded in the task he for one was very unwilling to admit. He had not studied Ould's book with sufficient care to know his views on the management of the third stage, but to the Dublin school this method of management of the third stage had long been credited, and in Spiegelberg's "Midwifery" it was alluded to as the Dublin method. The fact that Dr. Harvie described the method did not prove (although he must be given full credit for having used it in his own practice) that it originated in England. He could not help thinking that this practice had been known for a very long time, and in those early days they were not so keen to support their claims as originators because it was considered that they were generally admitted. He hoped that he might obtain evidence that this method of treating the third stage was in general practice in Ireland very shortly after Sir Fielding Ould's book was published, although not specially alluded to, because it was generally recognised. He considered it a pity that they should be deprived of the credit of what he believed to be the practice of the Dublin school for a very long time.—Sir WILLIAM SMYLY expressed their indebtedness to Dr. Kirkpatrick for his careful research. There was no doubt that the description published by Dr. Harvie was what was now generally known as the Dublin method, but credit was more often given to the person who popularised the method than to the person who first described it. The method appeared to be only mentioned by Dr. Harvie, who did not even appear to attach much importance to it, as he placed two other methods before it, whereas in Dublin it was exclusively and systematically taught for generations. When Spiegelberg visited this country he reported that the two things which impressed him most were the Dublin method of the delivery of the placenta and the use of chloroform in Edinburgh. Sir William Smyly did not think Credé's method was the same as the Dublin method; it was much more active and designed to get rid of the placenta as soon as possible. Sir William Smyly thought the very best method was the one referred to as being practised by primitive people—i.e., sitting in the crouched position and rubbing the hypogastrium with the hand, and he suggested that the Dublin method was an adaptation of that. After trying different methods he had come back to the Dublin method as the best.—Dr. TWEEDY said that all Dublin obstetricians had been accustomed to look upon Sir Fielding Ould as the founder of the Dublin method of dealing with the third stage of labour. The method was not described in Ould's book, which, however, was written when the author was only 21 years of age, and before he had acquired any practical experience in obstetrics. It was, therefore, quite possible that the method described by Harvie originated with Ould.—Professor A. J. SMITH said that he had gone through the literature to ascertain the claims of Dublin but he could get nothing but tradition to support it. Sir Arthur Macan, although very much in favour of German methods and literature, was convinced that this method originated in Dublin. Harvie's book did not come under their notice at the time. He agreed with Dr. Purefoy that the case was not proven.—Dr. KIRKPATRICK replied.

Dr. D. G. MADILL reported the After-results in 250 Cases of the Alexander-Adams Operation performed at the Rotunda Hospital during four years, and described the method of doing the operation with a single incision.—Professor SMITH said that in his own experience the type of case suitable for Alexander's operation hardly required an operation at all. Patients who came into St. Vincent's Hospital complaining of backward displacement, menorrhagia, and menstrual pain were first examined under an anæsthetic. If the uterus was found to be mobile a simple method of replacement was adopted by applying the weight of the ordinary Rotunda douche, which usually brought the uterus through the Bozeman's catheter into position. The patient was then put back to bed and examined on the third day; the uterus was usually found to remain in position. In that type of case the Alexander operation was usually performed, and gave good results in a limited class of cases, but he thought it would not do so if the uterus was enlarged.—Dr. TWEEDY said neither Dr. Madill nor anybody else could say that he had not been mistaken in bimanual examinations, and it was the possibility of these mistakes which robbed Alexander's operation of its value. Personally he favoured the operation of ventrosuspension, but his results from vaginal suspension had also been good. Nine patients on whom this operation had been performed all expressed themselves as having been improved, and four had become pregnant and delivered themselves normally. He thought Dr. Madill had curtailed the operation greatly when he suggested that it should not be done for sterility.—Dr. GIBBON FITZGIBBON thought that any operation for the cure of retroversion of the uterus would produce as good results as the statistics brought forward showed. He agreed with Dr. Tweedy that there were no complications after ventral suspension. He had never found any trouble arising afterwards in pregnancy or parturition. Out of seven cases in which he had done vaginal suspension during the child-bearing period, one afterwards had twins and two others had had single pregnancies, without complications. Many cases of retroverted mobile uterus caused no symptoms unless there was trouble in the tubes, in which case ventral suspension enabled an attempt to be made to correct the cause of the sterility. One came across adhesions of the tubes in cases with a mobile retroverted uterus, but with practically no thickening of the tubes which would be palpable by bimanual examination.—Dr. PUREFOY said Dr. Madill had pointed out to them the points of chief importance in the successful performance of the operation. During Dr. Purefoy's Mastership at the Rotunda this operation had not come into general use there, and he was against it because a woman came into the hospital and said that that was the third miscarriage she had since she had this operation performed by the inventor in Liverpool. He had on several occasions since seen the operation performed in the Rotunda Hospital, and he thought Dr. Madill's statement a powerful one for the operation in the cases he had indicated.—Dr. B. SOLOMONS said that in cases of prolapse of the uterus, in addition to plastic work by the vagina, he considered Alexander's operation very useful. In cases in which the retroversion occurred post partum, and where palliative treatment failed to produce a cure, an Alexander-Adams operation was most suitable. He suggested if either Alexander's operation or ventral suspension were properly performed there would be very little difference in the results. He found that the Alexander-Adams operation was effective in producing a cure without inserting a pessary afterwards.—The PRESIDENT said that in dealing with mobile retrodisplacement three classes of cases generally came under consideration. Firstly, the unmarried woman with uncomplicated retrodisplacement. These patients had no symptoms which could be attributed to displacement, and correction of the displacement was not necessary. Secondly, the married woman bearing children and suffering, as many did, from retrodisplacement complicated with descent, associated with definite discomfort. Examination under anæsthesia and the absence of history of infection enabled adnexal trouble to be excluded, and in these cases vaginal repair with correction of the displacement by the Alexander-Adams operation gave excellent results. Thirdly, the sterile married woman. If a transverse incision were made the tubes might be examined and treated, and the Alexander-Adams operation performed without difficulty. He preferred the Alexander-Adams operation to ventral suspension because relapse was not so liable after parturition, and the position obtained is more normal.—Dr. MADILL, in reply, said that he had seen Sir William Smyly perform a modified Gilliam's operation that morning, and it appeared to have most of the advantages of the Alexander, and, in addition, there was the extra advantage of seeing the inside of the abdomen. He admitted that a weak point was that one could not be absolutely certain, but he was glad to have the support of the President that one could be fairly certain after examination under an anæsthetic. He had nothing to urge against ventral suspension, except to doubt that the uterus remained in position after confinement. If there was no recurrence he was certain it was a better operation than the Alexander-Adams.

Reviews and Notices of Books.

Archbold's Lunacy and Mental Deficiency.
By JAMES WILLIAM GREIG, of Lincoln's Inn, K.C., and WILLIAM H. GATTIE, of Gray's Inn, Barrister-at-Law. Fifth edition. London: Butterworth and Co. and Shaw and Sons. 1915. Pp. 1058. Price 36*s.* net.

THE medical practitioner who comes in contact with the treatment of insanity and the formalities accompanying the custody of the insane only as incidents of his general practice will hardly need to provide himself with so exhaustive and weighty a volume as this. It is, however, otherwise with officers of county and borough asylums or their committees, who, doubtless, will be willing to defray the cost, and with those who, being the proprietors of licensed houses, have to be constantly and unremittingly certain of their ground in dealing with patients with regard to whom the law exercises proper and necessary vigilance. For such as these "Archbold's Lunacy" is a leading and authoritative text-book of the law, and if it has been somewhat augmented in its physical weight and bulk by the inclusion of the Mental Deficiency Act, and contains many pages which will not closely concern him whose professional work is the purely medical care of the insane, it is nevertheless a compendious treatise to which reference may have to be made at any time, when unexpected points arise, as well as on occasions of more usual occurrence.

How far the single-volume form may be preserved without inconvenience when there is ample material for two more readily handled volumes will be a matter for editorial consideration, as the subjects to be dealt with increase periodically and become more or less naturally divisible. The editors in the present case point out that the law of lunacy, so far as it is governed by the principal Act, that of 1890, divides itself into two chief groups of provisions. The first consists of those which are to be administered by the Commissioners and the Board of Control (constituted by the Mental Deficiency Act), by justices of the peace, county and borough councils, guardians of the poor and their officers, officers of county and borough asylums, managing committees and officers of hospitals, visitors, proprietors, and officers of licensed houses, and persons having the charge or being the medical attendants of single patients. The second group is those administered by the Lord Chancellor and the judges for the time being entrusted with the care of the persons and estates of lunatics, and by the masters in lunacy, Chancery visitors, committees, and medical attendants of lunatics so found, and by persons exercising, under the authority of the above higher officials, powers over the property of lunatics not so found, resembling those exercised by the committee of the estate of a lunatic who has been so found. How far this classification might lend itself to a two-volume form in the work in question is a matter worth considering, even though the use of a decidedly large book where a smaller one could be made available is only a matter of temporary inconvenience to the individual. There are, however, branches of the law of lunacy, included in such Acts as the Criminal Lunatics Acts, the Lunatics' Removal (India) Act, 1851, the Colonial Prisoners' Removal Act, 1884, and the Criminal Lunatic Asylums Act, 1860, which fill a good many pages to which recourse would be had only by lawyers in connexion with one particular phase of insanity and still less often by medical practitioners, from whose point of view we are regarding the subject.

The Mental Deficiency Act and the provisional regulations made under it are, no doubt, the most important addition to their previous work which the present editors of Archbold's Lunacy have had to make, and will be found to constitute a new part, "Part III."; the previous arrangement, by which Part I. dealt with the Lunacy Acts of 1890 and 1891, and with matters of cognate character, and Part II. with Criminal Lunacy, being retained. A brief introductory note preceding the Mental Deficiency Act calls attention to its scope and general outline in clear and succinct terms, and the explanatory notes to the sections of that Act should be of use to all who have to deal with a new piece of legislation, the interpretation of which has yet to become matter for direct judicial decision. In addition to the Mental Deficiency Act there have also been passed since the last edition of this work was issued, the Lunacy Acts, 1908 and 1911, the Asylums Officers' Superannuation Act, 1909, and the Lancashire County (Lunatic Asylums) Act, 1902. As well as these statutes, new rules and alterations of rules have had to be recorded.

Atmospheric Air in Relation to Tuberculosis.

By Guy Hinsdale, A.M., M.D., Hot Springs, Virginia. City of Washington: Published by the Smithsonian Institution. 1914. Pp. 136.

This volume is one of nearly a hundred essays entered in competition for a prize of $1500 offered by the Smithsonian Institution for the best treatise "On the Relation of Atmospheric Air to Tuberculosis," which was presented in connexion with the International Congress on Tuberculosis held in Washington in 1908. The essays were submitted to a committee of award, and the prize was divided equally between Dr. Hinsdale and Dr. S. A. Knopf, of New York City. At the request of this institution Dr. Hinsdale has revised his essay so as to indicate some of the advances made in the study of the subject during recent years, with the result that he has published an interesting monograph on aerotherapy in relation to tuberculosis.

An account is given of the influence of the air of forests, of inland seas and lakes, and of sea air on pulmonary tuberculosis. The effects of compressed and rarefied air and of high and low atmospheric pressure are also considered. Dr. Hinsdale takes a broad view of the value of climate in the treatment of tuberculous disease. He does not claim that there is any specific climate, and considers that the long search for such a climate is apparently at an end. He maintains, however, and his contention will be endorsed by most physicians, that climate may be utilised as an adjuvant of great value for carrying out the hygienic and dietetic treatment of all forms of tuberculosis. He also rightly points out that there are some elements of climate that have a more positive influence in hastening cures than others. Undoubtedly the first place among these must be assigned to an abundance of air, as nearly as possible bacteriologically and chemically pure. The value of sunshine is also insisted on, and Dr. Hinsdale believes that the moral effect of a large number of bright, sunny days is very great.

The questions of temperature and of the amount of moisture in the atmosphere are duly discussed, and the conclusion is arrived at that probably the best combination is a low humidity and a moderately cool atmosphere. As far as altitude is concerned, Dr. Hinsdale expresses the opinion that it probably has not, *per se*, any great influence. A comparison of the statistics from sanatoriums situated on the sea-level and at various heights tends to corroborate this view.

There is much that is interesting in this volume; it is well written and illustrated by a large number of plates, mainly reproduced photographs of institutions for the treatment of tuberculosis.

A Text-book of Radiology.

By E. Reginald Morton, M.D. London: Henry Kimpton. 1915. Pp. 221. Price 7*s.* 6*d.* net.

This is a very valuable addition to the more recent literature dealing with X rays and their use in diagnosis and treatment. It is essentially a practical handbook and, whilst it is obviously written with a full appreciation of the difficulties which beset the path of one who is beginning to work at X rays, the information is so arranged that it will be of the greatest service to that part of the medical profession which relies on the radiologist for aid in the diagnosis of medical and surgical conditions depending upon structural abnormalities of the skeleton and viscera.

Roughly speaking, the book may be regarded as consisting of three parts. The first deals with the elements of electrical principles as applicable to X ray apparatus. This part of the book is the least noteworthy, and perhaps a little more space might have been devoted to information about the various sources of electrical supply—e.g., primary batteries, accumulators, dynamos, &c., and the methods of distribution and modification of electric supply from generating stations; a little more also might with advantage have been added about the means of measuring electricity and the instruments in use for that purpose.

The second part consists of an excellent account of all such apparatus as is essential to an up-to-date installation. This information is very full, and explains lucidly the latest improvements both in instruments and in the methods of using them to the best advantage. It concludes with a useful chapter on regional radiography. Chapters XIII. to XV. are full of information on the latest knowledge concerning the pathological anatomy of the digestive, vascular, and excretory systems, illustrated by many excellent X ray photographs and diagrams which carry conviction with them. This is by far the most original and interesting part of the book, and deserves careful and close study. The last chapter is devoted to X ray therapeutics, and contains valuable instruction on dosage and other practical details.

The book is well printed, the illustrations are excellent, it is of a handy size, and neatly bound.

An Index of Symptoms.

By Ralph Winnington Leftwich, M.D. Aberd. Fifth edition. London: Smith, Elder, and Co. 1915. Pp. 516. Price 10*s.* 6*d.* net.

The fifth edition of this excellent work has been brought up to date by the inclusion of many new tests, of a number of new symptoms, and by amplification of the interlinear notes. But substantially the book remains the same valuable compilation as heretofore, one which the practitioner, be he junior or senior, will find a constant help in his daily work. The various notes are most sensible, and in many instances are of the obvious kind that makes the reader say, "Why did I never think of that before?" For example, in section 1261, The Intellect, Dr. Leftwich says, "Unaccustomed environment may give a false impression of dulness. As the sheep is clever enough on its ancestral mountains, but is dull on the plains, so the yokel seems dull in a town and the townsman scarcely less so in the country. Deafness also gives a false impression of dulness." This is a very necessary caution to bear in mind.

There is one paragraph concerning which we must join issue with Dr. Leftwich—namely, No. 1396, headed Parergiæ. The paragraph deals with phenomena such as Babinski's fan sign, and Dr. Leftwich rightly says that though this and other similar phenomena are generally classed as reflexes the two differ very essentially. "A term implying collateral action is preferable, and the writer suggests Parergia (*πάρα ἔργον*)." There is a perfectly good Greek noun, *πάρεργον*, meaning a by work, and it is needless and inaccurate to convert this into a Latin feminine. So we suggest the use of parergon for the singular and of parerga for the plural. We are sure that Dr. Leftwich would not speak of protozoæ. This, however, is a small blemish in an otherwise admirable compilation.

A Text-book of Physiological Chemistry.

By OLOF HAMMARSTEN, Emeritus Professor of Medical and Physiological Chemistry in the University of Upsala. With the collaboration of S. G. HEDIN, Professor of Medical and Physiological Chemistry in the University of Upsala. Authorised translation from the author's enlarged and revised eighth German edition, by JOHN A. MANDEL, Sc.D., Professor of Chemistry in the New York University and Bellevue Hospital Medical College. Seventh edition. New York: John Wiley and Sons; London: Chapman and Hall. 1914. Pp. 1026. Price 17*s.* net.

THE advances made in physiological chemistry, or, as some prefer to call it, biological chemistry, are so rapid that even a text-book written a year ago requires in many of its chapters to be recast, and the voluminous title-page of this work indicates alike its growth and the evolution of the science with which it deals. The veteran Professor Hammarsten, now in his seventy-third year, has felt the impossibility of keeping abreast for more than a certain number of years with the developments of physiology, and has adopted as a collaborator his successor Professor Hedin, who is responsible for the revision and reconstruction of the following chapters: I., On General and Physico-Chemistry; III., Carbohydrates; VIII., Digestion; XII., Organs of Generation; and XVI., Respiration and Oxidation. The other chapters were dealt with by Professor Hammarsten himself. Practically the general plan of the work remains unchanged. Some of the facts about oxidation have found a more appropriate setting than heretofore.

The first chapter deals with subjects on the zone common to physics and chemistry, such as osmotic pressure, colloids, catalysis, enzymes and ions, and salt action, just those subjects to which the average medical student pays the minimum attention. Under protein substances we notice that the term "albuminoids" is retained to include keratins, elastins, collagens, gluten, and reticulin, substances which in English text-books are usually grouped as sclero-proteins. Again, while we generally use the term protein, its precursor proteid is here sometimes used. Protamines are treated as true members of the group. Under coagulation of the blood we find the statement that coagulation "is prevented by the injection of an effusion of the mouth of the officinal leech" (p. 251). We did not find specific details about the so-called "biological reaction."

It should be stated that as in previous editions there are no illustrations, save one plate of blood spectra. Elaborate methods are no doubt purposely omitted, though the usual tests for many substances are given. In footnotes to each chapter full and sufficient references to the literature are given. The index of authors is very long, running to 36 pages, while the general index occupies 43 pages.

This work gives a straightforward, very readable, and succinct account of physiological chemistry. It is not overloaded with details and elaborate methods. In relation to certain important methods the principle of the method is stated. We can cordially recommend it as an excellent survey of chemical phenomena and facts in their physiological aspects.

Know Thyself.

By BERNARDINO VARISCO. Translated by GUGLIELMO SALVADORI. London: George Allen and Unwin, Limited. 1915. Pp. 327. Price 10*s.* 6*d.* net.

THE author takes as his text the saying of St. Thomas, "Intelligendo se, intelligit omnia alia." But whereas St. Thomas applied the words to God, Professor Varisco believes them to be applicable to human beings. He endeavours to show that by knowing himself he knows everything else as well. He is inspired to deny even the existence of any sphere of the Unknowable. The doctrine of an Unknowable he regards as a philosophic absurdity, although an inevitable result of scientific methods of inquiry.

The attitude is somewhat presumptuous. St. Thomas did but endeavour to define in an epigram the attributes of God. But the proposition that Professor Varisco's or anyone else's personality is of so all-embracing a description that knowledge of it implies a knowledge of everything else in heaven and earth is one which is neither reasonable nor justified by its results. A perusal of Professor Varisco's work indicates an apparent failure to "know" either himself or any of the main characters of the human mind. On his own principles his attempt to unveil the mysteries of the Unknowable breaks down on its unstable foundations.

Professor Varisco is not the first to imagine that the possibilities of the universe are limited by the narrow confines of his own soul, but he has learnt no lesson from the unbroken failures of his predecessors. He cannot reconcile himself to the conclusion of science, that there are some things which man cannot know. He will not reconcile himself to that conclusion because it is a disagreeable conclusion, which he would gladly see otherwise. So little does he really know himself that he makes his personal sentiments and predilections the test of truth and reality; he cannot disprove the conclusions of science, so he denies that the method of science is the correct method of reaching conclusions. If he were to apply in practical life his doctrines of "theoretic philosophy"—if he proposed to drive a steam engine or to treat a patient simply by knowledge of himself—his career would be brief. He is prudent enough to question the authority of science only in those regions which science has abandoned to the Unknowable. If Professor Varisco's views were to prevail we should be plunged once more in the darkness which preceded the work of Francis Bacon, for Bacon spread the doctrine that truth was to be found by looking outside at the things around us, instead of inside into our own minds. As things are, works like that of Professor Varisco cannot but accelerate the collapse of much verbiage and casuistry which is dignified by the name of metaphysics.

LIBRARY TABLE.

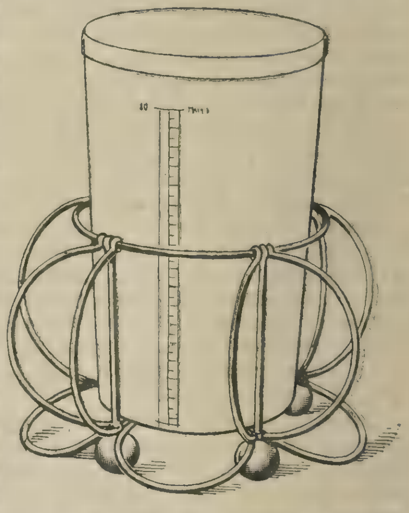
Studies in Questions Relating to Eye-training. By William Phillips, M.A., Professor of Education at the University College of South Wales and Monmouthshire, Cardiff. London, Glasgow, and Bombay: Blackie and Son, Limited. 1914. Pp. 138. Price 1*s.* 6*d.* net.—The term "eye-training" has been used loosely in pædagogic circles, and many teachers and others have been led to think that the efficiency of the eye as an optical instrument can be increased by training or special exercises. Hence much ingenuity has been expended on devising exercises—woodwork, sloyd, and so on—and much of the pupil's time has been occupied with them. So far as medical men conversant with the structure and physiology of the eye and its neuro-muscular apparatus are concerned, it was unnecessary to write a book to disprove the obviously faulty thesis. Such "eye-training" is a training of the mental eye and may so far be of great value. The book, however, small as it is, is packed with information of the greatest interest to medical men, especially to ophthalmologists. The author wanders along some fascinating by-paths. He deals, for instance, with the vision of the savage as compared with that of the civilised man, the supposed heightened sensitiveness of the blind and deaf, women's supposed special sensitiveness to colour differences, the peculiarities of animal vision, and the physiology and psychology of visual perception. He has read widely and studied deeply, and he has shown excellent judgment in his reasoning and conclusions, which are clearly and concisely set forth. The scientific accuracy throughout the work is remarkable, seeing that the author is a teacher who has presumably had no medical training. He may perhaps have been saved some errors by Dr. W. H. R. Rivers, to whom he expresses his indebtedness for reading through the proofs. We have noted one or two doubtful statements, but they do not seriously impair the value of the book. The longest chapter deals with school hygiene, with special relation to myopia. It contains some useful references to statistics. Some of the statistics quoted convey the impression that the author regards a visual acuity below 6/6 as necessarily due to myopia. If this be so, it nullifies much of the argument, but we may be mistaken. In any case this should be placed beyond doubt in a future edition. We warmly recommend the book, which has a much wider appeal than its title indicates.

Burdett's Hospitals and Charities, 1915: the Year Book of Philanthropy and Hospital Annual. By Sir Henry Burdett, K.C.B., K.C.V.O. London: The Scientific Press, Limited. Pp. 988. Price 10*s.* 6*d.* net.—This volume no longer needs detailed description. As a concise review of the position and requirements of the various charities dealt with, and as a trustworthy guide to British, American, and colonial hospitals and asylums, medical schools and colleges, nursing and convalescent institutions, consumption sanatoriums, religious and benevolent institutions and dispensaries, it deservedly occupies a very high place, and to say that it is indispensable in no way exaggerates its importance. A valuable part of the book is the record of hospital work for the year, and the chapter devoted to the future outlook and extension of voluntary hospitals will repay very careful perusal. Sir Henry Burdett believes that the Government cannot do without the help of the voluntary hospitals, and that it must face the twofold demand upon these institutions for the treatment of Government cases arising out of the National Insurance Act and from the war. With regard to the first matter, the editor points out that the year 1915 may prove memorable in the history and development of voluntary hospitals throughout the country; for in this year the first valuation under the National Insurance Acts will take place, and it is anticipated that the deficiencies which may have occurred will necessitate fresh legislation. In regard to the second matter, it is noted that the war has entailed heavy additional burdens upon the voluntary hospitals through the admission of large numbers of sick and wounded sailors and soldiers, that these burdens will become heavier as the war proceeds, and that no definite or adequate provision has yet been made by the Government to defray the cost of treating the sick and wounded in the voluntary institutions. That the situation is a grave one is shown by the fact that at the end of 1914 the financial position of the voluntary hospitals "represents an extra expenditure of not less than one million sterling, and probably in the whole may approximate two millions, which extra expenditure is due principally to new legislation, extra taxation, and the war."

New Inventions.

A NEW SPUTUM CUP AND HOLDER.

The chief features of this sputum cup and holder are indicated in the accompanying figure. The cup, which is made of waxed paper, has attached to it a cover of similar material. It does not require sterilisation, as a new cup is used every day, the soiled cup being burnt with its contents. But it is easily knocked over when used alone, and it was to get over this difficulty that the holder was made. I originally designed the holder for use at the Royal Hospital for Diseases of the Chest, City-road, E.C. It is a structure of wire resting on steel balls. Owing to its low centre of gravity and to certain wire loops it cannot be upset. It has four double handles, so that it can be readily and firmly grasped. It can be sterilised by means of boiling water as often as may prove necessary, but it is not likely to be contaminated with sputum by a patient with cleanly habits.



The waxed paper cup is made by Mono Service Vessels, Limited, Park Royal, London, W., and the sputum-cup-holder by Messrs. H. F. Angus and Co., 83, Wigmore-street, W.

H. E. Symes-Thompson, M.D. Cantab., M.R.C.P. Lond., M.R.C.S.

Cavendish-square, W.

THE LANCET.

LONDON: SATURDAY, APRIL 17, 1915.

Drink and Prohibition.

NATIONS, like individuals, are often forced in crises of their fortunes to take prompt and decisive action with regard to problems which in less strenuous times they have regarded as far too difficult and complex to be dealt with save after prolonged study and deliberation, and by partial and tentative measures. That is the situation at the present moment in this country with regard to the drink question. Under the stress of the formidable struggle in which we are now engaged we have been compelled to recognise that alcoholism is impairing our national efficiency in a degree which, even if we make full allowance for the exaggeration of prejudiced statement, constitutes a real and serious danger. It is natural that under such circumstances there should be a demand for heroic measures, and within the last few weeks the suggestion has been put forward in various quarters that the solution of the difficulty is to be found in the absolute prohibition of alcoholic liquors. While the advocates of this radical method are doubtless justified in their belief that, if it could be carried into effect, it would certainly meet the alcoholic danger, it is not quite clear that they have taken due account of the disturbing influence which its adoption would exercise on the economic life of the community, and for this reason we welcome the announcement that a strong committee has been appointed to assist the Government in its decision, and has been granted full powers to deal with the alcohol situation as a whole. Financial disturbance would not, of course, merit consideration if there were no other means than prohibition for enforcing national sobriety. But if the desired result can be attained by less violent measures it would obviously be preferable to avoid introducing any fresh sources of confusion in a time of crisis, and this is the thing which the new committee has to settle upon all the evidence available.

The problem has arisen more particularly in connexion with the efficiency of labour in the manufacture of munitions of war, in the shipbuilding yards, and in the transport industry. It has been asserted by large employers of labour engaged in the armaments trade and in shipbuilding that there has been culpable slackness on the part of a section of the workmen employed on the vitally important tasks of producing ammunition and repairing vessels of war, and that this slackness is largely due to excessive drinking. There appears to be no question as to the accuracy of the facts in relation to some centres of labour, though opinions may differ as to the proportion of workmen who lie under this censure, and as to the extent to which other factors, and notably the factor of overstrain, may have contributed to the production of inefficiency. And, however regrettable it may be that such a cause should be operative in a time of national emergency, there is nothing novel or surprising in the fact that alcoholism is unduly prevalent amongst the workmen engaged in the industries to which we have referred. As was pointed out some years ago, the practice and tradition of industrial drinking—that is to say, of drinking as an aid to muscular work—are nowhere more firmly established than in the class of casual dock labourers and amongst iron-workers, and in the latter group it is precisely in the semi-casual class of marine repairing engineers that this type of alcoholism is especially rife. The war, by withdrawing to active service a large number of the efficient and robust men engaged in the metal trades and in shipbuilding, gave to the less fit and less energetic men, and to the men employed by small masters with laxer standards of work and sobriety, the chance of being taken on in the larger and better class factories and yards; and naturally the greatly increased demand for war material operated in the same direction. As a result these men, accustomed to the use of alcohol as an industrial stimulant, and urged on to increased effort in the general speeding-up of work, carried into their new jobs the drinking habits which, not yet extinct even in the works of large employers, flourish freely in the lower ranks of these trades; and so the tradition of industrial alcoholism would naturally be spread and strengthened. It is hardly necessary to add that under such conditions the liberal wages paid in this period of booming trade furnished ample opportunity for convivial excess with further aggravation of slackness and inefficiency. It is a matter for regret that until the present crisis temperance reformers have for the most part given singularly little attention to this aspect of the drink question, and that their efforts have never been directed with much energy to combating this, by far the gravest and most intractable form of alcoholism. In this, as in so many other matters, we are suffering in time of war for our lack of organisation in time of peace. If the provision of adequate canteen arrangements had been more stringently enforced, if employers had been educated by appeals to their self-interest to prevent the introduction of liquor on their works, and if some of the energy applied to securing the early closing of public-houses had been directed to preventing their early opening, much might have been done to break the force of the tradition of industrial drinking to which the present discreditable state of affairs is so largely due. The whole subject has been dealt with by Dr. W. C. SULLIVAN in a work entitled "Alcoholism, a Chapter in Social Pathology," which at the present moment is a very illuminating treatise.

Modest measures, such as those just enumerated, may yet serve a useful purpose, but it is obvious that to combat the dangers of the existing crisis it is necessary to have recourse to more drastic remedies. And of these remedies the most effectual would undoubtedly be the prohibition of distilled spirits. It is chiefly in the form of spirits, especially as gin or whisky, that alcohol is taken in industrial drinking; at all events, in the metal industries and in the shipbuilding yards. Amongst other advantages that spirits possess for this purpose, their portability and the comparative ease with which they can be smuggled into workshops, give them a special attractiveness to the industrial drinker. And we may note here that limitations of the hours of public-houses tend in the same way to enhance the value of spirits and lead to their increased consumption in lieu of beer. At Cardiff, for instance, it has been observed that one effect of the early closing regulations which came into force last September has been to cause an appreciable increase in the sale of bottled spirits, and the same thing has probably occurred elsewhere. On this ground, then, as well as on account of their more deleterious effect on health, spirits are in a special category, and their suppression would be free from the risks and inconvenience that might result from complete prohibition. Moreover, the prohibition of spirits would be practicable, while all experience goes to show that complete prohibition cannot be made a reality without the support of a united public opinion; and when it is not a reality it means, as a rule, an increased use of the stronger and more injurious alcoholic liquors, and the development of an illegal traffic which corrupts public morality. On the whole, therefore, it seems reasonable to conclude that the exigencies of the present situation do not justify any such measure as absolute prohibition, but that the prohibition of spirits would probably lead to a considerable diminution of the alcoholism which is impairing the industrial efficiency of the armament factories and the ship-yards. And we may add, as a further argument in support of this policy, that the more limited measure of abolishing the sale of spirits is not likely to produce any such reaction to intemperance at the end of the war as would in all probability follow on the cessation of a temporary system of complete prohibition. This danger would be even less likely to arise if the present exceptional opportunity were seized to reorganise the public-house on rational lines as a place of decent resort.

"Frost-Bite" or Trench-foot.

ONE of the most striking of the illnesses from which our troops have suffered at the front has been that condition to which the name of "frost-bite" has been applied for want of a better appellation. It is to be hoped that the knowledge of this serious condition which our medical officers in the army now possess will lead to the consideration and formulation of preventive measures ready for adoption in future need. With the advent of spring this new scourge of armies is disappearing, as we are informed by Sir JOHN FRENCH'S last despatch, but it is most important that we should learn from the severe lessons that we have received in the matter, if only because no one can say that in the ensuing winter we shall not want to draw upon our information. The number of the papers and letters on the subject which have appeared in the columns of THE LANCET has testified to the interest which has been excited amongst our surgeons by the appearance of these lesions, and by the questions as to their etiology, their prevention, and their treatment. The views held by many observers are held in common, and give us trustworthy directions as to cause and treatment, at any rate; anything like systematic prevention could not be attempted this winter, for the trouble was not foreseen until it arrived.

The term "frost-bite" is not accurate, for all observers are agreed that this form of injury to the feet may occur when the temperature is above the freezing-point—in fact, according to one observer, frost was present in not more than 10 per cent. of the cases. The most severe lesions, however, seem to have been produced in those cases which were exposed to frost after getting thoroughly wet. A further point indicating that frost in itself has but little to do with causing this condition is to be found in the fact that the hands, the nose, and the ears, which are so very liable to suffer from true frost-bite, have escaped almost entirely in these patients. When we search for some predisposing cause we cannot find it in the general nutrition of the men, for in nearly every case the nutrition of the men has been good; in numerous instances the patients had been for some weeks receiving better food than was their wont. But undoubtedly in many cases a want of sleep, and a condition of nerve strain, may have assisted the appearance of the affection of the feet. What name should be applied to the condition is a difficult question, especially as those who are most acquainted with the subject are by no means unanimous as to the exact method of its production. Various names have been suggested, and amongst them may be mentioned chilled foot, trench-foot, trench frost-bite, boot-bite, and water-bite. It is better to employ a non-connotative name, and on the whole the term trench-foot appears to us to be the most suitable for a condition which has practically only been met with in those who have had to remain for long periods in the trenches. While there is no complete unanimity among those who have studied the matter as to the mode of production of the trench-foot, it is generally agreed that some interference with the circulation in all the tissues of the foot has been the most important factor. This interference comes mainly from the boots and from the puttees. If the boots are tight, then they will exert undue pressure on the feet, and this harmful pressure will be still greater if the attempt is made to obtain greater warmth by the use of two pairs of socks. The pressure will also be greater when the boots have become wet and hard. The pressure exerted by puttees is also of importance. If the soldier, in order to prevent the puttees from slipping down, applies them too tightly, they will interfere with the circulation; but even if, in the first place, they have been applied with no undue tightness, the action of the prolonged immersion in water will tend to make them tighter than they were, and so the pressure becomes greater. In addition to this interference with the whole circulation of the foot, the capillary circulation of the surface will be slowed by the cold, even though the temperature is well above the freezing-point, and the capillaries are contracted also by the cold. Then follows some exudation from the blood-vessels, and this exudation presses on the vessels from which it has come, and thus the circulation is still more obstructed. Another factor must not be disregarded: the men remain for many hours in the trench with hardly any bodily movement, the muscles are inactive, and the assistance which the circulation ordinarily receives from the movements of the muscles is not afforded, so that in this way also the circulation is still more hampered.

Such being in all probability the mode of production of trench-foot, as the very numerous reports which have reached us concur in believing, we must consider its treatment both remedial and prophylactic. To deal with the condition in its milder forms but little active treatment is needed. Two papers in THE LANCET this week describe the routine followed at different centres, and it will be seen that in the main it is similar. The patient should stay in bed, with the feet raised on a pillow, so as to favour the return of blood. In most cases the patients suffer less from pain if the feet are not bandaged at all; for keeping the feet warm usually increases the suffering, though there are exceptions to this rule. When there is no breach of surface, or the injury is slight, nothing more is required, but when bullæ are present some mild antiseptic application is required. Those that have been found of value are very numerous, so the surgeon has a wide choice, and the exact substance employed seems to matter little. When gangrene has occurred it seems to be clear that any early removal of the necrosed portions is undesirable, and even when the line of demarcation has formed the skin is generally much more extensively destroyed than are the deeper tissues, so that the total amount which has to be removed is generally very much less than might be thought at first, and the cases are few indeed in which a formal amputation is required. In cases where there is much pain it is essential that good sleep should be obtained, as on this the patient's general condition often mainly depends. Important, however, though the treatment of trench-foot is, still more important is its prevention, and this, of course, is what we now have to think of especially. We have to consider the possibility of another winter campaign, and we must be prepared in time for a condition which is new in military surgery, and is produced by new general tactics and circumstances. At first sight it appears that warmer clothing to the foot is the one thing needful, but this in itself may prove a danger. The wearing of two pairs of socks in boots that are only large enough for one will have a great tendency to interfere with the circulation of the blood, and this may lead to the trench-foot which it was intended to avoid. There must be general orders in respect of puttees; it could be pointed out that they may easily be wound too tightly round the legs, when they will interfere with the circulation. The boots must be loose; it is always advisable for the soldier to have the boots a size larger than he usually wears. The ideal wear for the foot in the trenches, loose-fitting wading boots, must be in many places impossible, as the soldier has not only to live in the trenches but also to march and charge. The expense has been mentioned as an objection to the supply of wading boots; but we do not think that this can be really put forward as an objection, if their use would prevent the invaliding of the thousands of men who have been suffering from trench-foot. All these points, most of them quite obvious, are now in the possession of the authorities, and we may be sure that organised steps will be taken in time to prevent a recurrence among our troops of a painful and distressing malady which has deprived us of the services of many otherwise able fighting men.

◆

Medical Officers of Health and the Army.

WE publish in another column an abstract of a document issued this week by the Local Government Board, entitled "Circulars and Papers relating to the Coöperation of Civil and Military Authorities in Sanitary Matters." This document deserves the close attention both of members of the civil public health service and of army medical officers, and should remove doubt, if any exists, as to the active part which the War Office desires civil medical officers of health to take in looking after the sanitary welfare of troops in camps or billets in this country. A previous circular, on which we commented in our issue of Oct. 31st, 1914, set out the position in this matter, which was then agreed to by both Government departments. Civil medical officers of health were to be consulted by the military authorities on the establishment of camps, or the arrangement of billets; their visits were to be encouraged, and in matters of importance they were authorised to make direct representations to the Deputy Director of Medical Services of the command concerned as well as to the Local Government Board. Arrangements were to be made wherever practicable through the county and sanitary authorities, and their public health officials, for the utilisation of isolation hospitals by the troops, for interchange of information as to infectious diseases, for disinfecting blankets and clothing, and generally for the undertaking of "sanitary services."

The scheme, which has been organised by the Local Government Board and directed by the medical inspectors of that department, has evidently developed considerably in importance and utility. The document now issued contains departmental letters of various dates settling the procedure in such questions as the payment from army funds of the charges of local authorities, the remuneration of sanitary officers, the arrangements for additions to civil isolation hospitals for the reception of military cases, and the inspection of food supplies. A series of notes on the "Inspection of Billets, Camps, &c., by Medical Officers of Health" sets out in a practical form some of the principal points to be attended to on these inspections, the importance of which has been illustrated by recent experience. Among these we note directions as to the method of communicating with the military authorities, and the condemnation of billets, or the reduction of the number of men in billets, on account of insufficient floor space, defective ventilation, insufficient lavatory, water-closet, or latrine accommodation, and other sanitary defects. It is requested that special attention should be given to cook-houses and places of food storage and messing-rooms, and it is stated to be essential that the medical officer of health should draw the attention of the officer commanding the troops to any uncleanliness of floors, tables, or feeding utensils. Small posts like guards at waterworks and bridges should not be overlooked, while camps are to be specially inspected, particularly in regard to overcrowding and to the method and efficiency of disposal of excreta, urine, sullage water, and food refuse. Directions of this kind are opportune at a time when large new movements of troops in the country are expected, and when new bodies of men, with a medical staff necessarily unfamiliar with the units under its charge and the sanitary requirements of the places were they are quartered, will be replacing forces going overseas.

In an article on the relations between the civil and military authorities which have existed during the war, published elsewhere in this issue of THE LANCET (p. 818), there will be found a letter addressed to the Local Government Board of the highest interest. In this letter, which also appears in the latest circular of the Board, the Army Council has expressed the opinion that the assistance which local public health authorities, and particularly their expert officers, have already rendered in the unexampled circumstances of the last eight months has been invaluable in safeguarding the health of the forces and in preventing the spread of infectious disease, and requests that the thanks of the War Office may be conveyed to the councils of the counties, boroughs, and sanitary districts concerned for the work thus performed. We are confident that these commendations have been well earned, and they will be read with satisfaction by medical officers of health who, perhaps against their personal inclination, have remained at their civil posts in the belief that by turning their special knowledge to its best use in the localities in which they act they are giving good service to the army as well as to the public health of the country generally, which it is so important to maintain at the present time. We do not for a moment urge that the public health service of the country should in all respects go on "as usual." Some branches of the work, such as that of medical inspection of school children, can be substantially reduced; younger men acting as assistant officers for tuberculosis dispensaries or isolation hospitals can be replaced by senior men and undertake army service, as many have done already. Factory chimneys may be allowed to go unwatched for a while, and routine housing inspection and other ordinarily necessary matters may well be curtailed. But epidemics must not only be met if they arise, but must be prevented with all possible vigilance, and dangerous environmental conditions must be as vigilantly sought out and dealt with as in times of peace. This means that the maintenance of an efficient public health service at home is essential, and it is well to have on record at this juncture that this necessity is as strongly realised by the army authorities as by the central civil public health department.

Annotations.

"Ne quid nimis."

THE SUPPLY OF DRUGS AS AFFECTED BY THE WAR.

WE have heard perhaps too much of the shortage of drugs. As a matter of fact, when we remember the extent to which this country had allowed itself to become dependent upon Germany for its supply of drugs, it is remarkable that after eight months of war there should be hardly any drugs of importance that are not obtainable in at least small quantities. Notwithstanding the steady drain on stocks that has been going on all this time, and the fact that the main source of direct supply has been cut off, it is really astonishing to find that drugs which up to the end of July last had been obtained almost exclusively from Germany can still be secured in reasonable quantities. Prices have naturally advanced very seriously, and some drugs, as stated in THE LANCET of March 20th (p. 625), are seven or eight times as dear as they were before the war. But the important question is not one of the price of drugs, but of being able to obtain them, and at the present time it would be possible to secure at least a small supply of almost any recognised medicinal product without great difficulty. This result is due to two main causes—namely, the importation of drugs from neutral countries, and the wise and prompt measures taken by the Government in consultation with medical and pharmaceutical authorities to husband the drug supply. In the scheme for conserving our stocks of medicinal products the individual members of the medical profession have played a very useful part, and there is every reason to believe that medical men have loyally coöperated with the professional committee appointed by the Government in August last[1] by acting upon the suggestions made by the committee with regard to the economical prescribing of those drugs which appeared in the earliest stage of the war to be likely to become scarce. It was already foreseen that supplies of such products as the salicylates, the bromides, and potash salts might in due course be insufficient for a normal demand; but since the beginning of August experience has shown that there are other drugs which must be used with economy, while owing to the receipt of consignments of bromides from the United States there does not appear at the moment any need to put these drugs into the same class as the salicylates for example; although it cannot be foreseen whether the imported supplies of bromides will continue indefinitely. Among the drugs of which stocks are now low and difficult to replenish are the following: Carbolic acid, salicylate of soda, salicylic acid, acetylsalicylic acid, salol, novocaine, eucaine hydrochloride, benzamine lactate, atropine, thymol, barbitone, better known under its familiar name of veronal, paraldehyde, phenazone, and phenacetin. These, together with lanolin, constitute a list of drugs which, in the opinion of the medical committee above referred to, should be prescribed with economy, although it is not to be inferred that the drugs named are so scarce that they should be withheld in cases in which they are really needed. The reason for the inclusion of carbolic acid in the list is that it is required for war purposes, but there is not the slightest reason why carbolic acid should not continue to be prescribed as usual for internal administration since the quantity required is extremely small; similarly, weak solutions for gargles and other parallel uses would absorb a comparatively minute quantity of the available stock. When large quantities of disinfectants and antiseptics are required, however, it would be advisable to substitute where possible one or other of the many germicidal preparations of which supplies are plentiful, as, for instance, cresol soap solution. As to salicylic acid and the salicylates, the strictest economy is undoubtedly indicated for the present; there is a probability that supplies of these drugs will be rather more plentiful in due course, but in the meantime stocks are very low. There is, however, such a large consumption of acetylsalicylic acid by people who "doctor" themselves that the economical prescribing of this drug by the medical profession will not be very effective, and it is unfortunate that some reasonable means cannot be devised to prevent the wastage of this product at the present time; it is little use for the medical profession to be economical if the public is extravagant. As regards local anæsthetics, there is a fair supply of cocaine. But even cocaine is becoming scarcer and dearer and should therefore be prescribed economically. The scarcity of atropine is serious, and the present outlook for increased supplies is not hopeful; the shortage is not due to the absence of the raw material, for belladonna root and leaves are perhaps less scarce than they were a short time ago, supplies having arrived from the Balkans. There is still, of course, the hope of further supplies of atropine from neutral countries and of the alkaloid being produced here, but in the meantime the advice of the committee to prescribe it with the strictest regard for economy should be followed. For barbitone some other hypnotic can be substituted in most cases, while there are other antipyretics which can be prescribed instead of phenazone and phenacetin. The scarcity of lanolin is perhaps not very pronounced, as this ointment base is now being made in this country; but other bases can be employed quite successfully, and it is understood that the Germans are using as a substitute soft paraffin with from 5 to 10 per cent. of beeswax. The list of drugs that should be used economically has been recently made the subject of a communication to all medical men; the list is drawn up on sound principles, and if the medical profession continues to coöperate in conserving supplies of the indicated drugs there need be no inconvenience from the cutting off of German supplies.

LOWER DEATH-RATE *V.* LOWER BIRTH-RATE.

THE effect which the war will have in diminishing the birth-rate throughout the kingdom cannot at present be estimated. That it must be considerable admits of no question, and the maintenance of the supply of human beings necessary for the re-establishment of the nation's prosperity is likely to be a source of anxiety to this and coming generations. In this connexion it is pointed out by those interested in the prevention of infant mortality that if little can be done to increase the number of births by causing married couples to realise the importance of bringing children into the world, from the point of view of safeguarding their country's prosperity, much, nevertheless, may be achieved in the direction of protecting those lives of infants which under existing social conditions are sacrificed. The National Association for the Prevention of Infant Mortality and for the Welfare of Infancy has issued its annual report for 1914 from its offices at 4, Tavistock-square, W.C., and will no doubt welcome all accessions to its membership and contributions to its funds. In the *Manchester Guardian* we notice an interesting correspondence has taken place, among the contributors to which have been Lady Selborne and Mr. J. R. Ormerod. The former, quoting from statistics of 1911, gives the rate of deaths in their first year of children born in New Zealand as 58 per 1000, and the rate here as 130 per 1000, and invites us not to waste the lives that we produce. The latter suggests, as a step towards the desired end, the extension of medical benefits under the Insurance Acts to all children. This he regards as a natural sequence to the granting of maternity benefit, which, he observes, needs to be revised and perhaps extended. Subject to the condition that this can be done without exploiting the medical profession, and with the offer of proportionate consideration for increased services rendered, we should say that practical good might result from it. Another possible contribution to the same result is urged in a letter by Dr. Barbara Tchaykovsky, who "feels very strongly that the first step in any baby-saving crusade just now is the immediate placing of the Notification of Births Act on the Statute-book as a compulsory measure throughout the kingdom." This step, Dr. Tchaykovsky believes, would assist the work done by municipal health visiting agencies, voluntary health societies, and kindred organisations, and would tend to help the newly born infant through the first month of life, in which one-third of the present infant mortality occurs. The same writer calls attention to the probability of a large increase in the births of illegitimate children occurring in the neighbourhood of military camps and to the possibility of preventing by sympathetic measures a "veritable slaughter of the innocents." The whole subject, no doubt, is one of great importance, and, moreover, is one which, if it is to be attended to effectively, must be taken in hand without delay, for, as we have observed, the extent to which the numerical increase of the population will be interfered with by the war is now a matter as to which we can only speculate. All that we know is that possibly the next few months will witness slaughter of the flower of the nation's manhood as great as that which has already taken place, and that while we await with bated breath the result of the struggle, we may be able also to do something to mitigate its inevitable and dire consequences.

CONVULSIONS DURING PERTUSSIS: CURE BY PUNCTURE OF THE LATERAL VENTRICLE.

THE following case is reported by Dr. Louis Fischer in the *New York Medical Journal* (1914, vol. c., p. 1054). A baby, aged 8 months, suffered from an ordinary attack of whooping-cough for two weeks, when it began to have both tonic and clonic convulsions. These continued for two days, convulsions recurring at one time every six hours. They were not relieved by injections of chloral hydrate and potassium bromide per rectum. Nor did chloroform anæsthesia afford relief. Lumbar puncture, too, proved unsuccessful. It was decided to aspirate the right ventricle of the brain. The frontal lobe was pierced through the anterior fontanelle, and 22 c.c. of an almost clear cerebrospinal fluid were withdrawn. The convulsions ceased and the baby made a complete recovery. The aspirating needle recommended is 3·2 inches in length, introduced downwards and towards the median line at an angle of about 20 degrees to the depth of about 1·8 inches. The needle then enters the lateral frontal portion of the ventricle.

THE POLICE AND ALLEGED LUNATICS.

A LETTER addressed to the *Times* of April 8th by Mr. Holcombe Ingleby, M.P., is calculated to raise grave doubts as to whether the discretionary powers given to the police by Section 20 of the Lunacy Act, 1890, may not in some respects be wider than the safety of the public and of alleged lunatics demands. At any rate, it should receive consideration from those to whom the treatment of persons supposed to be in the early stages of insanity is a matter of interest. Although there are, no doubt, two sides to the story which Mr. Ingleby has told, with apparent fairness, from one point of view, it is difficult to see how any modification of detail can affect the main points raised by his narrative. To recite briefly the facts of the case, an elderly lady went to Scotland Yard to report her suspicion of the presence of German spies in the neighbourhood of the boarding-house where she lived. The rank of the official with whom she had her interview is not stated, and what took place between them is left to our imagination, but as a result the police then and there arrested the lady and conveyed her to a workhouse, in which institution she was kept until on the third day she was released by the authority of the justice of the peace before whom she was brought, this being within the limit of time prescribed by the Act. The Chief Commissioner, in a letter written to the lady after her release, said, "Of course, inquiry shows that this (the removal to the workhouse) was wholly unnecessary, and I need hardly say how greatly I regret the inconvenience and distress of mind caused to you by the action of one of my officers." The Chief Commissioner has also authorised the statement that the police officials acted in strict accordance with their duty as laid down by the law, as well as with consideration and kindness towards the lady, and that Mr. Ingleby's statement of the case was not in accord in all particulars with the facts as known to himself. It appears from Mr. Ingleby's letter that no legal action is likely to be taken by the lady, further particulars of whose adventure will be found in the document referred to. Possibly it might be difficult for her to recover damages. Section 20, referred to above, under which, presumably, the police acted, provides that: "If a constable, relieving officer, or overseer is satisfied that it is necessary for the public safety or the welfare of an alleged lunatic with regard to whom it is his duty to take any proceedings under this Act that the alleged lunatic should before any such proceedings can be taken be placed under care and control, the constable, relieving officer, or overseer may remove the alleged lunatic to the workhouse of the union where the alleged lunatic is, and the master of the workhouse shall ...... receive and relieve, and detain the alleged lunatic therein, but no person shall be so detained for more than three days, and before the expiration of that time the constable, relieving officer, or overseer shall take such proceedings with regard to the alleged lunatic as are required by this Act." Apparently this section was complied with; it does not say that it is the duty of the officer to take reasonable care to satisfy himself that it is necessary to remove the alleged lunatic; as long as he is himself satisfied that is enough.[1] There is no obligation or recommendation to call in a medical practitioner, and, indeed, to do so does not relieve the officer of his responsibility.[2] It would appear, then, that the police in this matter acted strictly in accordance with the law, as the Chief Commissioner claims that they did. At the same time, with the passage above quoted from Sir Edward Henry's letter to the lady before us, we are driven to the conclusion that a somewhat marked lack of sound judgment and discretion was exhibited at Scotland Yard, where, if anywhere in the United Kingdom, "the constable" might be expected to display judgment and discretion, or to have access to higher authorities for the direction of his actions. Further, if information was given of her predicament to the lady's relatives or friends, it only had the effect of bringing them to the workhouse on the third day. Mr. Ingleby seems to be of the opinion that there was undue delay in communicating with them, and we must remember that in London communication can usually be made both easily and rapidly if desired. As a result, therefore, of the police taking steps, authorised by the law, and taken by them, no doubt, with the best intentions possible, a lady, probably not in robust health, who may have suffered from an exaggerated apprehension with regard to German spies, but who hardly on that account alone could have been dangerous to herself or to the public, suffered 52 hours' confinement as a pauper lunatic. The medical man who attended her in the workhouse did not, it is stated, regard her as insane, but had no power to order her release; and in due course the magistrate, who, acting in strict accordance with the law, seems to make a practice of attending every three days at the workhouse in question, put an end to a situation which ought never to have arisen. Why there should be no provision for the summoning of a medical man at the earliest possible moment to decide what in some cases may be a simple question, but may in many instances be beyond the scope of the intelligence and training of a constable, relieving officer, or overseer, is by no means plain. The law as it stands may afford a convenient and effective means for placing promptly under observation or control cases brought to the notice of the police; but the law would be strengthened not weakened in its effectiveness if the calling in of a medical practitioner, whenever this was possible, were also enjoined, so as to shift the responsibility to the shoulders best adapted for the burden.

PLASTIC TRACHEITIS AND BRONCHITIS.

IN the *Medical Journal of Australia* of Feb. 13th Dr. H. Laurie and Dr. H. C. Colville have reported a case of a very rare condition—plastic tracheitis and bronchitis. A married woman, aged 45 years, was taken to the Alfred Hospital, Sydney, with the diagnosis of œdema of the glottis due to chronic nephritis. She was of stout build and was suffering from urgent dyspnœa accompanied by marked whistling stridor. There were cyanosis and retraction of the neck and intercostal spaces. Preparations were made for tracheotomy, but she improved slightly. Her colour returned and the retraction diminished, although the whistling stridor was still marked. A more thorough investigation was then made. The patient had been well until a week before admission when she contracted a "bad cough." This got worse until three days before, when the dyspnœa began. She had always been healthy except for an attack of rheumatism in the previous winter. The temperature was 99° F. and the pulse 100. The heart sounds were inaudible. No adventitious sounds could be detected over the lungs. The vesicular murmur was very weak. The point of maximum intensity of the stridor was over the manubrium sterni and not over the larynx, as would have been expected in œdema of the glottis. Pulv. jalapæ co. was given, and six leeches, followed by a hot pack, were applied to the front of the neck. The patient's condition remained much the same for four hours, and then, in a severe spell of coughing, a blood-stained cylindrical cast about 2 in. long and nearly ¾ in. in diameter was expelled. It appeared to have been formed in the trachea. The dyspnœa at once improved. The question of diphtheria immediately arose. A swab was taken from the throat and found to contain a pure culture of Hoffmann's bacillus. The breathing continued to improve, and on the following night a similar cast was expelled, consisting of a complete mould of the trachea and right and left bronchi. Further improvement followed and the patient could speak in a whisper. During the next few days small fragments of similar membrane were coughed up and rhonchi were heard over the front of the right lung near its root. The expectoration for several days was profuse and at first blood-stained. The voice gradually returned, and the patient was discharged ten days after admission feeling well except for a little huskiness and a slight cough. In plastic bronchitis, according to Dr. William Ewart, the condition is confined to the smaller bronchi—"from the tubes of the diameter of a goose-quill (rarely of much larger size) down to the finest ramifications." In this case the trachea, both main bronchi, and the larger tubes on the right side were affected. The smaller bronchi and bronchioles were absolutely free.

TRANSFERENCE OF THE HUTCHINSON MUSEUM TO AMERICA.

THE closing of the Polyclinic has been followed by the acquisition of the Hutchinson Museum by the Johns Hopkins Medical School. The loss to this country of the remarkable and unique collection of original drawings, coloured plates, and photographs, which represent the life-work of one of the greatest clinicians of the age, is to be deplored. Though the value of drawings has been recognised since the earliest times of clinical study, excepting the splendid collection of wax models at the St. Louis Hospital, Paris, no previous attempt had been made to illustrate systematically the appearances of disease in the living subject. No practising surgeon has approached Sir Jonathan Hutchinson in the number of types of disease he observed, described, and, whenever possible, illustrated pictorially. In the opening address delivered at the Polyclinic in 1900 on Post-Graduate Study,[1] Sir William Osler said of him: "He is the only great generalised specialist which the profession has produced, and his works are a storehouse upon which the surgeon, the physician, the neurologist, the dermatologist, and other specialists freely draw." The collection consists of: (1) Original coloured drawings, of which there are many hundreds; (2) coloured plates taken from atlases, books, and memoirs; (3) engravings, woodcuts, photographs, and pencil sketches, very often with the letterpress or manuscript notes attached. They illustrate the whole range of medicine and surgery, but particularly the life work of the collector in syphilis and skin diseases. It is "probably the most remarkable iconography on syphilis ever made." Taken at random, the labels on some of the rarer items show the minuteness with which this protean disease is illustrated: circumcision chancres, syphilitic herpes, recurrent chancres, vaccination syphilis, keloid. While regretting the loss to our country of this valuable and unique collection, we are pleased that it has found a home in the most famous of the American medical schools where, perhaps, it may be put to greater use than here, as the teaching which it embodies must be less familiar, but those who have had the pleasure of seeing the remarkable and enthusiastic man who made this collection employ it in teaching will feel that in its demonstration there will be one irreparable loss. However rare the case sent to Hutchinson he could parallel it from his collection of portraits, and from the vast storehouse of a most tenacious memory relate histories. For the conventional labelling of a malady with a name, which is called diagnosis, he had almost a contempt. His plan was to take type cases, to describe them in detail, to illustrate them whenever possible by drawings, and to place similar cases beside them. His object always was to discover causes rather than to name. With all this minuteness he combined a wide and bold philosophic grasp. No clinician ever focused light from so many sources on a subject. From the rare case he passed to the other rare cases of the same kind in his knowledge, then perhaps he passed to another field of disease, regarded as entirely different and showed analogies unsuspected, or he passed to the ordinary and showed that it and the extraordinary were only phases of the same process. Or, moving still more widely, he illuminated the subject by an illustration from plant pathology or from ordinary life or by a quotation from the poets.

[1] THE LANCET, June 12th, 1900, p. 73.

PUNCTURE OF THE CORPUS CALLOSUM AS A DECOMPRESSIVE MEASURE.

The ordinary results of temporal decompression for brain tumour are only partially satisfactory; it is suggested that only 10 per cent. of such cases are operated upon with success. There are especially to be considered in these cases the extremely severe headaches and vomiting which form such distressing features, and any measure which can relieve these symptoms must be welcomed, whether or not such a procedure is associated with more extensive proceedings directed to the tumour mass itself. An operation of this nature has been practised with considerable success; it consists in puncture of the corpus callosum, and the technique is not held to be very difficult. It has for its object the relief of tension in the ventricles in the brain, a condition which is held to be largely responsible for the symptoms—a condition, in fact, allied to internal hydrocephalus present in many cases of brain tumour. Such relief is effected by allowing communication between the ventricles and the subdural space superior to the corpus callosum. Dr. Elsberg, discussing his results at a meeting of the American Neurological Association on May 7th, 1914,[1] stated that he had had 30 cases, and in more than half of them the general symptoms had been markedly relieved by the operation. No matter what the pressure conditions within the skull the operation did good. Where, however, there was no internal hydrocephalus the procedure was useless. He also stated that radical removal of the tumour should be done wherever possible; decompression has its field as a temporising method or in non-removable or non-localisable intracranial neoplasms. As regards the dangers of the operation, these are not great. He quotes von Brahmann as having done 57 operations without any ill effect, and Dr. Elsberg himself had done 39 without mortality. Further results by more observers will be awaited with interest.

Parliament resumed sitting on Wednesday, April 14th.

---

[1] Journal of Nervous and Mental Diseases, 1914, vol. xli., p. 726.

The late Augustus William Dalby, L.R.C.P., L.R.C.S. Edin.—Mr. Dalby, a highly respected medical practitioner at Frome, Somerset, died recently at Weymouth. After qualifying as L.R.C.P. and L.R.C.S. Edin. in 1884, he commenced practice in Frome, and was for many years medical officer of health for the Frome rural district. He was an enthusiastic Volunteer, and was lieutenant-colonel of the 2nd South-Western Mounted Brigade Field Ambulance.

PUBLIC HEALTH OFFICERS AND THE WAR.

The question of granting leave of absence to medical officers of health, assistant medical officers of health, medical officers of isolation hospitals, and tuberculosis officers, who have obtained the permission of their councils to accept temporary appointments in the army, is one that has exercised many of the officers concerned and their authorities, and frequent allusions to it have appeared in our columns. We have made inquiries as to the practice of the Local Government Board in giving permission to the officers to take such leave of absence, and the attitude of the Board will be clearly seen by what follows.

The Local Government Board sent the following circular letter to the county councils and sanitary authorities on August 12th last:—

> Local Government Board, Whitehall, S.W.,
> 12th August, 1914.
>
> Sir,—The Local Government Board wish to draw the attention of local authorities to the great importance of maintaining the efficiency of the sanitary service of the country at the present time. In many areas the medical officers of health and other officers engaged in public health work will be giving their services to the navy or army, and it will be necessary for the local authority to make other arrangements for carrying on their work. It is essential that there should be no relaxation of the activities of local authorities in the prevention and control of epidemic diseases, the protection of water-supplies from contamination, and the promotion of child-welfare, and in securing the wholesomeness of food-supplies and the general sanitary condition of each area. On this account it is important that all vacancies in the minor sanitary staff should be filled up.
>
> The actual steps which may be open to local authorities to replace medical officers of health who are absent on naval or military duty will vary in different districts. In many areas adequate temporary arrangements may be made by coöperation between the county and district authorities or between neighbouring district authorities. The Board will be glad to be informed of each case in which a medical officer of health or chief sanitary inspector or inspector of nuisances has been given leave of absence for naval and military service, and of the steps taken to arrange for the temporary discharge of his duties.
>
> I am, Sir, your obedient Servant,
> (Signed) H. C. Monro, Secretary.

Since then nearly 100 whole-time medical officers of health out of a total of 314 have, with the consent of their councils and of the Board, taken temporary commissions in the Royal Army Medical Corps. About the same number of part-time medical officers of health and many medical men holding other posts under county councils and sanitary authorities have also given their services to the army. Each application to the War Office from a medical officer employed by a local authority is, in accordance with an arrangement made between the two departments, referred to the Local Government Board as to whether the medical officer making the application can properly be spared from his civil duties. So far it has not been necessary for the Board to object to the granting of a temporary commission to any medical officer who has applied, as in each case temporary arrangements have been made for carrying on the officer's work.

From the beginning of the war local authorities and their sanitary officials have rendered valuable assistance to the military authorities which the Army Council have acknowledged in the following letter from the Assistant Secretary to the Army Council, which appears in a circular issued by the Local Government Board this week to county councils, sanitary authorities, port sanitary authorities, and medical officers of health, an abstract of which will be found on p. 833 of this issue of THE LANCET:—

War Office, London, S.W., March 25th, 1915.

SIR,—I am commanded by the Army Council to inform you that they have had under consideration the assistance which local public health authorities, under the guidance of the Local Government Board, have rendered since the outbreak of the war to troops stationed in their administrative areas. They are of opinion that this assistance in the unexampled circumstances of the last eight months has been invaluable in safeguarding the health of the forces and in preventing the spread of infectious disease to an extent which would have been otherwise impracticable, and I am to ask that the Local Government Board will be so good as to convey to the councils of the counties, boroughs, and sanitary districts concerned the thanks of the Army Council for the work thus undertaken. I am in particular to refer to the valuable services which have been given by medical officers of health, sanitary inspectors, and other officials of the local authorities in coöperating with the army sanitary service.

The Army Council trust that during the coming summer months they may continue to secure the assistance, advice, and coöperation of these authorities and their expert officers, under the general supervision of the Board's medical inspectors, with a view to maintaining the present favourable record as to disease among troops stationed in camps and billets in the United Kingdom.

I am, Sir, your obedient Servant,
(Signed) B. B. CUBITT.

The Secretary, Local Government Board, Whitehall, S.W.

The Army Council concur with the Board in attaching great importance to the action taken by sanitary authorities and their officers in safeguarding the health of the forces and in preventing the spread of infectious disease, and they regard the action taken by sanitary authorities as an integral part of the precautionary measures necessary to protect the health of the troops at home. The Board are of opinion that serious risk of calamity would be involved if, during the coming months, sanitary authorities were to relax their efforts or were unable to take the necessary action because they are inadequately staffed or have only inexperienced officers.

Subject to these considerations the Board are assenting to proposals for medical officers to take service in the army whenever this can safely be done. The Board have accepted temporary arrangements whereby the services of a senior practitioner are substituted for those of a junior medical officer both for sanitary and for hospital work. The tuberculosis organisation in each county and county borough is largely concerned with the treatment of sick persons, and some arrangement must be made for carrying it on. There should therefore be, in every such area, a tuberculosis officer available to advise both the Council and the Insurance Committee for the area. As a rule it is not desirable that both the medical officer of health and the tuberculosis officer shall be absent from their duties. Where local authorities have given their officers leave of absence they have almost invariably done so on such terms as not to involve them in any financial loss or other disadvantage.

INFANT MORTALITY IN SOMERSET.—At the last meeting of the Somerset county council the medical officer of health, Dr. W. G. Savage, stated that during the past ten years the death-rate in the rural districts was 75·9 per 1000 of children under 1 year of age, and in urban districts 90·8, a low rate compared with the rate in the country generally.

SCOTLAND.

(FROM OUR OWN CORRESPONDENT.)

Edinburgh University Graduation Ceremony.

A GRADUATION ceremony in connexion with the University of Edinburgh was held on March 30th in the McEwan Hall, when the degrees were conferred by Principal Sir William Turner. The usual boisterous note of the students was lacking, the reason for the quiet and subdued nature of the proceedings being indicated, no doubt, by the presence among the graduates of a large number wearing His Majesty's uniform. For a spring graduation the numbers "capped" was unusually large. Sir William Turner, in his address to the graduates, said their ceremony that day was marked by an important difference from the ordinary graduation ceremonies which had been formerly held—the predominance of the military element. Not only were many of the graduates in uniform, but degrees had been conferred upon other graduates *in absentia* because the recipients of the degrees were either at the front or were otherwise engaged in the forces on active service. That was not the only point of interest, however, for the number of graduates at this season of the year was above the average, because the Senatus, acting, he might say, on behalf of the nation, had given opportunities to students to present themselves for graduation at this time instead of asking them to wait until the ordinary summer graduation. In giving this special privilege, the students had to show themselves in their examinations worthy of that special privilege. That was to say, the graduate must have attended all the courses of instruction before appearing for the degree, and had to pass, also, the examination with credit to himself and to the University. It was important that the public outside should know what had been done. How the war had reacted upon the academic life was evident from the fact that the University had had to part with about 1000 of its male students. The University had lost largely in its income, and more than 2000 of its students, graduates, and staff had joined the forces in one capacity or another. The University had been called upon to participate in a great national movement, and they owed a great deal to the Officers Training Corps, which was under the direct charge of a military committee of the University, having the sanction of the War Office. In this connexion he desired to look back as far as the year 1859, when there was a great national movement in connexion with a possible invasion. The nation was then stirred to resolve itself into a series of volunteer corps, and the students of to-day were doing only what their predecessors had done in 1859. The students of that day entered into the task with as much enthusiasm as the men of to-day, and the University students formed themselves into what was known as No. 4 Company, the great Edinburgh Battalion. He was a member of that company and a volunteer, and having served for 30 years in it he passed through the various grades of rank from the lowest which was then known as "ensign," now an obsolete rank. He claimed the Officers Training Corps as the direct descendant of No. 4 Company, for, if he was right in his recollections, the old volunteer company of the University was not disbanded when the disbandment of the volunteers took place under the new War Office régime, but was continued as the corps to which many of the students now belonged.

Drink and the War: Public Opinion in Edinburgh.

Edinburgh is not an industrial centre in the accepted sense of the term, and is not to any extent concerned in the production of munitions of war. Nevertheless, by reason of the fact that it is one of the leading brewing centres in the country, the proposed prohibition of the drink traffic, consequent on the state of affairs in the ship-building and other industrial areas, has for it a very special interest. It goes almost without saying that the licensed trade is strongly and unanimously against any measure of the kind that have been indicated. There is, in their opinion, no call for any such drastic action in Edinburgh, and naturally they do not care to distinguish between their own district and such areas as Clydeside. It is stated that drunkenness in the city, judged in the light of police statistics, is below the normal. While the majority of the opinions of those not directly concerned in the liquor trade appear to favour prohibition, there was an important section against any proposal of the kind. One leading public man declared that in his opinion this merely represented the thin edge of the wedge. "We are told," he said, "that this is to be only for the time being, but I am confident that an attempt will be made to make the prohibition a permanent thing. Experience abroad, and especially in America, has been that you get more drunkenness in the prohibitionist States than anywhere else." Another prominent citizen declared that his position was briefly this—to have a total prohibition of all spirituous liquors, such as whisky, brandy, and gin, but to make no such regulations regarding beer. It was his opinion that the riveters and men engaged in similar work must have drink of some kind, and he did not think the drinking of beer would in any way interfere with the work of production. He was convinced, however, that for such measures to be in the least efficacious they must be universal, applying to clubs no less than to public-houses. An interesting corroboration of his point of view was furnished by the head of one of the largest manufacturing firms in the district. The question of the stoppage of the whisky traffic was discussed at a soirée which was held by the employees, and the managing director was so much struck by the point of view which the men indicated that he there and then proposed that they should have a referendum on the subject. The ballot was secret, and the result was a vote of 90 per cent. in favour of prohibition of whisky until the war is over. The question of beer-drinking was not voted on. The men's views were admirably summed up by one of their speakers in the following manner: "The immediate completion of the war or its prolongation evidently now means a question between efficiency and inefficiency. If drink means inefficiency then drink must be stopped."

Views of Edinburgh Medical Men on the Drink Question.

From a number of interviews with medical men in Edinburgh representative opinions were obtained in regard to the effect of drink on the general efficiency of the worker. A prominent panel practitioner said that there had not been much increase in drinking during the war among working men, but he had observed that there had been a considerable increase in the consumption of liquor among a certain class of women in receipt of war money. "Edinburgh is not," he remarked, "like places in the west country with their big ship-building yards and engineering works. I would not say that men in Edinburgh are drinking more than they were before." Another leading medical man thought that as a rule long hours were not responsible for increased drinking among the workers. If a man got occasional or intermittent extra long hours he might find that drink would help him along, but if he were working a few extra hours a day regularly, provided he used his spare time with discretion, he did not find the necessity for a stimulant. It was more likely that extra wages had made some of the workers more prodigal of their money. He thought that there was no question that the medical profession would favour prohibition. Another practitioner, who at present has a panel list on which there are about 2000 names, said that he had only just come across his first case of a man being laid up through nervous strain, brought on by overwork since the beginning of the war. He did not believe for a moment that extra work was knocking down workers. With fair rest a man could get along nicely working 12 hours a day. Long hours, in his opinion, did not directly induce drinking. From his experience the war had not increased the incidence of drinking. He also mentioned the interesting fact that there had been less illness among the poor. He had the duty of examining applicants for parish outdoor relief in his district, and for the last month the number was 8, compared with 16 last year. There was more work, and they either did not bother about medical attention or the fact of being at work kept them well. A medical man with a large practice among the working-class population in the western district of the city said it had not been noticed that there had been any increase in drinking among the workers in the city since the outbreak of war. Work, and plenty of it, he believed to be one of the greatest aids to sobriety and good living. He was of opinion that total prohibition would be a mistake. Civilisation was not sufficiently far advanced at the present day to permit of that. If drinking was stopped altogether he thought the result would simply be that the evil tendencies of the worst elements of the population would break out in another direction, with probably the direst consequences. His own idea was that a much better plan would be for the Government to prohibit all strong drink, such as whisky, rum, and brandy, and permit the sale and consumption of beers of a very light alcoholic strength, and wines.

Edinburgh Royal Maternity and Simpson Memorial Hospital.

Dr. James Haig Ferguson has succeeded Dr. F. W. N. Haultain as physician on duty, and Dr. George F. Barbour Simpson has succeeded Dr. J. Lamond Lackie as assistant physician, both for the quarter to June 30th, 1915.

April 12th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Honorary Degrees at the National University.

HONORARY degrees were conferred by the Senate of the National University at its last meeting under unusual but distinctly interesting circumstances. Some 60 years ago there was founded in Dublin, under the rectorship of John Henry Newman, the Catholic University of Ireland; it consisted of several faculties, including medicine, but not having a charter it had no power to confer degrees. The Senate of the National University, considering the position of the past students of the Catholic University, conferred honorary degrees upon many who "having during their student days, for conscientious reasons, refrained from attending institutions where they could have obtained university degrees, and in place thereof having resorted to the Catholic University, which was unable to grant them that privilege." Among those who received degrees were the following medical men:—

LL.D. (*Honoris Causa*).—Lieutenant-Colonel John Joseph Crean, A.M.S.; Mr. George Unthank Macnamara; Surgeon-General Thomas Maunsell, C.B.; Dr. Joseph Francis O'Carroll; and Colonel James Patrick Rooney, R.A.M.C. *In absentia:* Mr. Nicholas Thomas Connolly; Right Hon. Michael Francis Cox, M.D.; Mr. William Creagh; Surgeon-General Sir Charles MacDonagh Cuffe, K.C.B.; Lieutenant-Colonel Charles Boromeo Jennings, A.M.S.; Lieutenant-Colonel Ignatius O'Farrell, A.M.S.; and Major Patrick Walter Stafford, A.M.S.

M.D. (*Honoris Causa*).—Mr. Thomas Joseph Crean, Mr. Nicholas Furlong, Mr. Thomas Laffan, Mr. John M'Cullagh, Mr. Charles Stennett Redmond, Sir Joseph Michael Redmond, Mr. Charles O'Lomasny Ronayne, Mr. John Ryan, and Mr. Denis Walshe. *In absentia:* Mr. Richard Cannon, Mr. Matthew Kearney, Mr. John Kilbride, Mr. Charles William M'Carthy, Mr. Constantine Joseph MacGuire, Mr. Thomas M'Kenna, Mr. Daniel Aloysius O'Sullivan, Mr. Joseph Quirke, Mr. James Patrick Ryan, and Mr. Edward Aloysius Stephenson.

Royal College of Physicians of Ireland.

At the last meeting of the Royal College of Physicians of Ireland Dr. J. J. Gannon was elected a Fellow of the College.

Cerebro-spinal Meningitis.

Since Dec. 8th, 1914, up to and inclusive of April 10th, 1915 (when 4 new cases were admitted), 47 patients were received into Purdysburn Municipal Fever Hospital, Belfast, with cerebro-spinal meningitis; while 3 were treated in the surrounding districts. Of these 50 cases of cerebro-spinal fever 10 have died, which gives a mortality of a little over 22 per cent. These cases have been treated with three varieties of serum—i.e., Flexner's, from the Rockefeller Institute, New York, Dopter's, from the Pasteur Institute, Paris, and Mulford's, from Philadelphia. It is too soon to give any opinion as to which of these serums affords the best results, though there seems to be a preference among practitioners for Flexner's. From the experience at Purdysburn Hospital it is clear that when serum is used within the first 24 hours of the onset of the disease infinitely better results are obtained; and, further, in cases in which the serum was used early recovery has taken place, even when within less than a day from the beginning of the attack the patient was covered with a petechial rash, and when on lumbar puncture the cerebro-spinal fluid was found to be purulent. It is therefore more prudent to risk sending a patient into hospital on a mistaken diagnosis than to wait for certainty, thereby depreciating the results of serum-therapy.

The late Samuel Hamilton, M.D. R.U.I.

Dr. Samuel Hamilton died suddenly, from angina pectoris, on April 4th, at his residence, Ballynahinch, co. Down. A sudden strain about a year ago warned him that his heart was not strong, and he thereupon gave up night work, but otherwise continued at work until two days before his death, when he developed a severe cold, during which two attacks of angina, the last a fatal one, occurred. Dr. Hamilton, who was a native of Dromara, studied at Queen's College, Belfast, where he graduated as M.D., M.Ch., of the Royal University in 1882, and M.A.O. in 1885, and was noted as an athlete. He settled in practice in Ballynahinch in his native district, where by his cheery manner and professional skill he obtained a large practice, and was greatly liked. In 1891 he married a daughter of Professor Witheron, D.D., of Londonderry, who, with two sons—one of whom is a lieutenant in the R.A.M.C.—survive him. Dr. Hamilton was buried in Dromara on April 6th.

Richard Crossett, L.R.C.P. & S. Edin.

The death is announced at his residence, Cookstown, co. Tyrone, of Mr. Richard Crossett, after a prolonged illness. A native of Londonderry, Mr. Crossett studied at Queen's College, Belfast, and in 1876 became a Licentiate of the Royal College of Physicians and Surgeons of Edinburgh. Forty years ago he began practice in Moneymore, but soon afterwards he removed to Cookstown, where he built up a large practice and where he has resided ever since. In addition to leading a busy professional life, he took his share in the public business of Cookstown, where for a time he was a town commissioner and for upwards of 30 years he was consulting sanitary officer of the Cookstown union. He retired from active practice four years ago.

April 12th.

NOTES FROM INDIA.

(FROM OUR OWN CORRESPONDENTS.)

Vaccine Treatment of Leprosy in India.

VACCINE for the treatment of leprosy, prepared from the streptothrix isolated by Major T. S. Beauchamp Williams, I.M.S., has been supplied by the Bombay Bacteriological Laboratory to various parts of India and other parts of the world. Owing to the slow progress of the disease, the recurring attacks of fever with extension of the leprosy lesion, and the periods of remission and temporary improvement even in untreated cases, it is difficult to arrive at any conclusion as to the usefulness of the vaccine as a method of treatment. Generally speaking, it may be said that some cases appear to improve under treatment, some remain stationary, while others show no improvement at all. A report by Major J. R. J. Tyrrell, I.M.S., Nowgong, shows that he had nine cases under treatment long enough to test the vaccine. Seven improved by treatment, while two showed slight, if any, change. None were any worse, and one had been under treatment for 10 months, one for eight, one for seven, two for four, two for three, and two for two months.

Plague in the Punjab: Iodine in the Treatment of Plague.

The plague returns for the month of February show that 23,389 deaths were reported in the province of the Punjab during the month, the weekly returns having been, Feb. 6th, 4492; Feb. 13th, 5285; Feb. 20th, 7798; and Feb. 27th, 5814. A decrease was thus disclosing itself at the end of the month, but throughout the period practically all parts of the province were affected.

The last report of the Bombay Bacteriological Laboratory includes an account of experiments made to test the efficiency of the treatment of plague cases by tincture of iodine. Some of the cases were treated by giving five drops of tincture of iodine every three hours by the mouth, while iodine was applied locally to the buboes. Others were treated by injecting seven minims of the tincture in saline solution intravenously once every 24 hours as recommended by Captain F. Powell Connor, I.M.S. A set of control cases were treated by the method ordinarily adopted by Dr. Choksey at the Mahratta Plague Hospital. Excluding the cases with many plague bacilli in their blood before treatment was commenced, there were 4 recoveries out of 9 cases among the control cases, 8 recoveries out of 12 cases treated by iodine by the mouth, and 3 recoveries out of 10 cases treated by iodine intravenously injected, the number of cases treated not being sufficiently large to allow definite conclusions to be drawn.

The Abuse of Cocaine in India: the Effect of the War.

Stewards and seamen of the Austrian-Lloyd boats have played a prominent rôle in the illicit trade in cocaine. The profits ensured to successful smugglers and retailers are far in excess of those accruing from dealings in any other form of intoxicant, for victims of the cocaine habit are prepared to pay extravagant prices for the gratification of their desires. Under the most favourable circumstances the supply is limited and fluctuating. The demand, on the other hand, is certain and constant, and hence prices are liable to violent fluctuations. A few years ago, when the Punjab Government followed the example of other provincial administrations and included cocaine in the list of prohibited intoxicants, an immediate and abnormal rise in prices ensued all over India. The supply had been cut off at one of its few remaining sources and retailers were as yet uncertain as to the success that would attend their smuggling projects. When achievement outstripped anticipation the prices fell. The war may be expected to reproduce these conditions in a more exaggerated form, even if it has not already done so. Communications with the old supplying firms have ceased, and many of the erstwhile smugglers are either fighting for their country or interned in foreign ports. New sources have to be discovered and new agents have to be engaged. In the meantime, the cocaine devotee will be put to many shifts to obtain his dose of injection. His field of inquiry will be enlarged and his chances of discovery proportionately increased. So also with the retailer. The certain prospect of enormous profits will tempt him to relax a little of his customary caution. He will approach every available source of supply, not forgetting the Government stocks. There may be a revival of direct negotiations with wholesale chemists, British and French firms taking the place of German and Austrian. Cocaine will be sent in a large consignment of other drugs under a false label, and invoices will be so manipulated as to deceive the Customs. Such methods are difficult to detect, but with a temporary depression in sea-borne trade the Customs establishment should be able to devote greater attention to the examination of consignments from doubtful firms to suspected consignees. The situation is thus peculiarly favourable to a repressive policy, and active coöperation between the Excise and Customs departments in all parts of India should lead to excellent results. If the Indian Government now fails to initiate a vigorous anti-cocaine campaign it may anticipate a progressive increase in the consumption of this dangerous poison as soon as normal conditions are re-established.

The Health of Bombay.

In his survey of the health of the city during the last year the executive health officer of Bombay comments on the improved health conditions in the city as portrayed in the decreased mortality from all causes, but reminds the corporation that in order still further to improve upon these results more consideration should be given to sanitary improvements that have been suggested. In times of epidemic the schemes for improvement of sanitary conditions in the city were readily enough sanctioned, but when health conditions were approaching those of a Western city the necessity for persisting in sanitary reform was apt to be lost sight of. He emphasises the fact that the steady decrease in mortality is not due to the outlay of large sums in sanitary improvement, for during the last 14 years no large outlay has been undertaken in Bombay. He refers in particular to insanitary areas in the city, regarding which a scheme of reform was presented to the corporation ten years ago, and if this scheme had been carried out and the areas improved, reduction in the mortality rate would have been more marked, the work of the health department would have been greatly facilitated, and the condition of the city would have been very much improved. Satisfactory as it may be to look back on the steady decline in mortality, in spite of many difficulties, it would have been more satisfactory to feel that alongside the work that has been done in organising, supervising, and controlling the public health administration of Bombay something substantial and permanent had been effected so as to maintain the position arrived at and create a lasting improvement in the public health of the city.

March 20th.

THE HEALTH OF THE NAVY IN 1913.

THE report on the health of the Royal Navy for 1913 is somewhat shorter than usual, owing to the absence of any original articles on professional subjects by medical officers; these are intended to be published in a naval medical journal, to be issued quarterly. There is also a general compression of material, on account of the mobilisation that took place in August last, when the report was being prepared.

Satisfactory Health Condition of the Navy.

The returns again show a continuous and satisfactory improvement. The total strength for the year 1913 was 126,830, an increase of 7290 over that for the previous year. Of this number, 103,730 were serving either in the Home Fleet or on the Home Station; the remaining 23,100 being distributed among the seven fleets and squadrons serving abroad. For the total force the ratio of sickness has been 610·5 cases per 1000 of strength, a considerable improvement compared with the ratio for the preceding five years 1908–12, which was 656·6. The average number of men daily on the sick list has been 23·79 per 1000, compared with 26·97; the deaths have been 3·24, compared with 3·23; and the final invalidings 13·53, compared with 16·23 per 1000. All of these ratios are also below those of the preceding year. The highest admission ratio was, as usual, on the East Indies Station, 998 per 1000. This was higher than the quinquennial ratio of 971 for 1908–12, and also higher than the ratio for 1912, which was 948. The death ratio on this station (10·8 per 1000) was also higher than the quinquennial ratio (9·25) and the ratio for 1912 (5·55). The highest ratio of daily sick in hospital, 33·27, also occurred on the East Indies Station, a rather lower figure than that for 1912, which was 33·51, but still much higher than the quinquennial average of 29·06. Next come the Home

Station with 28·59 per 1000 daily sick, and the Irregular List with 27·94. The healthiest command was the Mediterranean, with a ratio of 20·21 daily sick, the Home Fleet being nearly as healthy with 20·66, and the West Atlantic and Fourth Cruiser Squadron (formerly known as the North America and West Indies and Training Squadron) with 20·73 per 1000. The Home Station (consisting of depôts and training ships and hospitals) daily sick ratio of 28·59 was an improvement on the quinquennial average of 35·26 per 1000.

The most numerous admissions to hospital were, as usual, for diseases of the digestive system, in the ratio of 107 per 1000. Venereal diseases caused 93 admissions per 1000, a considerable improvement on the quinquennial average of 116, the chief reduction being in the prevalence of secondary syphilis. Of the most important diseases, pneumonia was the only one that showed a slight increase, 4·69, compared with 4·21 admissions per 1000. Malaria (3·5) and tuberculosis (1·93) were well below the quinquennial averages. There were only 4 cases of Mediterranean fever throughout the whole navy, with no death. The most fatal diseases were pneumonia (38 deaths), tuberculosis (34), enteric fever (31), and organic disease of the heart (21). The respective ratios, 0·29, 0·26, 0·24, and 0·16 per 1000, were slightly higher than the averages for tuberculosis and enteric fever, slightly lower for pneumonia and heart disease. The chief causes of invaliding were heart disease (2·07 per 1000), nervous diseases (1·76), and tuberculosis (1·64), showing slight reductions on the respective quinquennial averages.

Prevalence of the Chief Diseases.

Small-pox is thus referred to, on the *lucus a non lucendo* principle; it did not prevail anywhere. Only 5 cases occurred; 3 of these were on board the *Conqueror* at Devonport. The first was a man who had been on leave shortly before; all were mild cases, being modified by previous vaccination. One case occurred at Port Said and 1 at Shanghai; these also were mild cases, for the same reason. On each occasion the ship's company were revaccinated. No spread of the disease occurred in spite of the unavoidable close contact with the rest of the crew. Influenza (1324 cases) showed a continued reduction on previous years. It was of mild type, chiefly in the Home Fleet and Home Station and on the Australian Station; only one death occurred, owing to pneumonia. A few cases were admitted in all the commands, except at the Cape. There were 414 cases of scarlet fever, of which 321 were on the Home Station. Outbreaks occurred on the *Powerful* (94), the *Impregnable* (86), and at the Youths' Training Establishment (47). The origin was not traceable in either instance. The general character of the disease was mild, but cardiac failure caused death in 5 cases. Extensive epidemics of mumps are reported in the Plymouth training ships and establishments and elsewhere. Not only boys were affected, but on several ships many cases also occurred among stokers, especially on the *Vivid* and *Victory*.

There were 123 cases of diphtheria, with 5 deaths; 105 of these cases and all the deaths occurred on the Home Station. An outbreak of 33 cases on the *Impregnable* was due in the first instance to a boy who contracted the disease when on leave. Cases continued to appear from January until September, all among the boys, and it is regarded as probable that there were several separate infections. If this was the case it seems strange that effective measures were not taken to prevent spread of infection time after time. On the *Ganges* there were 18 cases and on the *Powerful* 11 cases, also considered to have been sporadic, having "apparently occurred at intervals throughout the year." Of 8 cases on the *Victory* 4 occurred amongst cooks' mates who slept in the same room; some explanation of this, with dates of onset, might have been afforded. Eight cases of cerebro-spinal fever were admitted, 4 being returned from the *Victory;* 2 occurred in March among stokers, the other 2 (a boy and a stoker) in April and May; in 3 of the cases no growth could be obtained from lumbar puncture. Two cases were reported from the *Pembroke* among stokers in April and May. Two other solitary cases were returned, one from the *Centurion*, the other from the *King George V*. Nothing could be traced as to source or mode of infection.

Enteric fever caused 123 admissions and 31 deaths; 34 cases were on the Home Station, 16 being from the *Vivid*, appearing at intervals. No source of infection was traced. For several years this ship, which is stationed at Plymouth, has had a heavy incidence of enteric fever. Ten cases occurred on the *Formidable* of the Home Fleet, on which ship there had also been some prevalence during 1912. Exhaustive investigation as to the origin of infection, and particularly as to the possibility of the presence of a carrier case on board, has not so far yielded any positive result. Only 4 cases of Mediterranean fever were admitted throughout the whole navy. One of these occurred at Malta, possibly due to eating goats' milk cheese. Another was a Maltese, an habitual drinker of unboiled goats' milk. The other two cases occurred in the Home Fleet, but are not alluded to in the remarks. Presumably they were not fresh cases, but readmissions. There were 62 cases of dysentery, of which 31 were returned from the China Station, occurring chiefly among men at Shanghai, Hong-Kong, and elsewhere during the revolutionary outbreak. No cases were fatal. Of the 31 China cases 10 were reported as amœbic and 6 as bacillary.

Pneumonia continues to be the most fatal disease in the navy. There were 38 deaths, giving a ratio of 0·29 per 1000, which is, however, lower than the quinquennial average of 0·33. The total number of cases was 595, of which 341 (with 24 deaths) were from the Home Station and 196 (with 11 deaths) from the Home Fleet: 78 were admitted from the *Impregnable*, 45 each from the *Ganges* and *Vivid*, and 43 from the *Pembroke*. No remarks are made as to possible causation or nature of the incidence; some information would have been acceptable on these points. There were 445 cases of malarial fever (3·5 per 1000), less than the quinquennial average (4·7), but more than in 1912 (2·55). 128 cases were admitted on the East Indies Station; 48 of these were from the Bombay Sailors' Home, which is situated in a malarial district, and in the grounds of which rain-water had been allowed to collect, forming a focus of infection. Tuberculosis continues to show a decline in prevalence; the admissions numbered 245, representing a ratio of 1·93 per 1000, compared with the quinquennial ratio of 2·59; and the daily sick 56, or 0·44, compared with 0·57 per 1000. In 191 out of the 245 cases the disease affected the lungs. The East Indies Station had the highest case ratio, 3·2 per 1000. The sick berth staff, with a ratio of 8·1, suffered much more than the other ratings, that for ordinary seamen being only 1·84 per 1000. Venereal diseases show an improvement in every particular; the admissions were 93·17 per 1000, compared with 116·02 in the preceding quinquennium. The constantly sick ratio was 5·19 as against 7·41, and the invaliding 0·81 compared with 1·20 per 1000. These affections caused most inefficiency on the China Station with an admission ratio of 151·11, while in the Home Fleet this was only 92·80 per 1000. Owing chiefly to improved methods of treatment there was much shorter average stay in hospital—i.e., less loss of service—than in previous years. Although the average strength of the navy has increased considerably, the total number of days lost to the service through sickness of this nature was less than in 1912 by 27,800 days, and less than in 1911 by 67,507 days.

There were 15 cases of beri-beri, 8 being reported on the *Perseus* in the Persian Gulf. Rats were found, and a mongoose, which was procured to kill the rats, after a month became paralysed, the various limbs, and finally the diaphragm being affected in turn. This suggests rat transmission; there was no undue rat mortality on board. Four cases of infection by Schistosomum japonicum were recorded from the China Station; 2 were officers who contracted the disease snipe-shooting in paddy fields, and 2 were engine-room artificers infected by wading in river water, with feet and legs bare, while applying a new propeller to the *Woodcock*. In these latter cases the incubation period was determined to be about 40 days. None of the men had waded in water over the knee-joint, so that infection did not occur per anum. There were 76 deaths from drowning, 10 of which occurred when a cutter belonging to the *Perseus* disappeared during bad weather in the Persian Gulf. There were 5 cases of wounds in action (one fatal), sustained during a punitive expedition on the Tungistan Coast.

The prompt appearance of this report, embodying the statistics of the preceding year derived from the most distant parts of the world, is very creditable to the departments concerned. As to the state of health of the Royal Navy, it can be described as most satisfactory.

A MONTHLY RECORD OF ATMOSPHERIC POLLUTION.

COMMITTEE FOR THE INVESTIGATION OF ATMOSPHERIC POLLUTION:

Summary of Reports for Month ending Jan. 31st, 1915.

1	2	3	4	5	6	7	8	9	10	11	12
Place.	Correspondent.	Rainfall in millimetres.	Metric tons of deposit per square kilometre during month.

Col. 4 includes all matter insoluble in water but soluble in CS_2. Col. 5 includes all combustible matter insoluble in water and in CS_2. Col. 6 includes all earthy matter, fuel, ash, &c. One metric ton per sq. kilometre is equivalent to: (*a*) Approx. 9lb. per acre; (*b*) 2·56 English tons per sq. mile; (*c*) one gramme per sq. metre; (*d*) 1/1000 millimetre of rainfall (see Col. 3).

The analytical work involved in these returns was undertaken respectively by J. F. Liverseege, F.I.C., Birmingham; Harry Hurst, B.Sc., F.I.C., Bolton; F. Southerden, B.Sc., F.I.C., Exeter; A. R. Tankard, F.I.C., Kingston-upon-Hull; W. H. Roberts, M.Sc., F.I.C., Liverpool; S. A. Vasey, F.I.C., Director, THE LANCET Laboratory (London Meteorological Office collections); J. H. Coste, F.I.C. (Embankment Gardens, Finsbury Park, Ravenscourt Park, Southwark Park, Wandsworth Common, Victoria Park collections), London; F. L. Teed, D.Sc., Golden-lane, London, E.C.; C. C. Duncan, F.I.C., Malvern; E. Knecht, Ph.D., M.Sc., Ancoats Hospital, Bowdon, Cheadle, Davyhulme, Fallowfield, Moss-side, Philips Park, Queen's Park, School of Technology, Whitefield (Manchester collections); J. T. Dunn, D.Sc., Newcastle-on-Tyne; Professor W. P. Wynne, Attercliffe Burial Ground, Hillsborough Park, Meersbrook Park, Weston Park (Sheffield collections); S. H. Davies, M.Sc., York; J. W. Biggart, F.I.C., Greenock; A. Scott Dodd, B.Sc., F.I.C., and R. M. Clark, B.Sc., Leith, Stirling, and Paisley respectively; Messrs. R. R. Tatlock and Thomson, Coatbridge. The correspondents referred to in col. 2 are for the most part public health authorities.

DEATH OF EDWARD THOMAS ERNEST HAMILTON, B.SC., M.D., M.S. LOND., F.R.C.S. ENG.—Dr. Hamilton died at his residence in Johannesburg, South Africa, on March 8th. He was born at Rathgar, near Dublin, in 1867, and was the son of a former surgeon in the Royal Navy. Entering Guy's in 1886, he became a distinguished student there, carrying off a large number of honours. He took the Conjoint qualification of the London Colleges in 1891. At London University he took the B.Sc. in 1889, the M.B., B.S. (first class honours in medicine and surgery) in 1892, the M.D. in 1893, and the M.S. in 1895. He became F.R.C.S. in 1893. He was for four or five years a demonstrator of anatomy at Guy's. In 1898 Dr. Hamilton went out to South Africa and started practice on the Rand. During the Boer War he served as medical officer on one of the hospital ships and in various hospitals ashore. After serving with the rank of major in the field during the recent rebellion Dr. Hamilton became principal medical officer at Swakopmund, the chief port of German South-West Africa, now in British occupation, where he developed an intestinal complaint, and, being much run down from pressure of work, he was ordered to Johannesburg to recuperate. There he became subject to attacks of mental depression, and it is supposed that in one of these fits he terminated his life, as he was found with a fatal bullet wound in his head. Much sympathy is felt for his widow. His funeral took place with military honours.

ROYAL COLLEGE OF SURGEONS OF ENGLAND.

MEETING OF COUNCIL.

A QUARTERLY meeting of the Council was held on April 8th, Sir W. WATSON CHEYNE, the President, being in the chair.

It was resolved :—

> That the best thanks of the Council be and are hereby given to Mr. Arthur H. Cheatle for presenting to the College his large collection of specimens illustrating the surgical anatomy of the temporal bone which the Council regard as a most valuable and useful addition to the Museum. The Council also desire to express to Mr. Cheatle their high appreciation of his services in arranging and cataloguing the whole series of otological specimens, and to record their grateful sense of the care and attention which Mr. Cheatle had so freely devoted to this task.

It was also resolved :—

> That the best thanks of the Council be and are hereby given to Mr. Alban Doran for his valuable services in arranging and cataloguing the obstetrical and gynæcological instruments in the Museum.

In accordance with the recommendation of the Jacksonian Committee the Jacksonian prize for the year 1914 was awarded to the writer of the essay bearing the motto: "With the Help of a Surgeon He Might yet Recover." When the envelope bearing this motto was opened it contained the name of Mr. Jonathan Hutchinson. The subject of the essay was the Pathology, Diagnosis, and Treatment of Trigeminal Neuralgia.

It was resolved that the subject for the Jacksonian prize for the year 1916 should be the Methods and Results of Transplantation of Bone in the Repair of Defects caused by Injury or Disease.

The John Tomes prize was awarded to Mr. James Frank Collier for his scientific work on Comparative Dental Anatomy and Pathology.

In accordance with a report of the examiners in anatomy under the Conjoint Board, it was resolved to appoint Mr. Joseph Clinton Collins, of the London Hospital Medical School, the Begley student for the ensuing three years.

The Council elected to the Fellowship the following two Members of 20 years' standing: Mr. Frederick George Larkin, of Grove Park, and Professor Johnson Symington, of Belfast.

Sir Alfred Pearce Gould was re-elected the representative of the College on the Senate of the University of London.

Dr. G. Bellingham Smith was appointed the representative of the College on the managing committee of the British Hospital for Mothers and Babies at Woolwich.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

Philip Norman Button has been appointed Surgeon for temporary service in His Majesty's Fleet.

The undermentioned have been granted a temporary commission as Surgeons in His Majesty's Fleet:—Robert Henry Herdman Newton, William Ernest Boyd, and William Francis Bowen.

The following appointments have been notified :—Temporary Surgeons: H. A. Hewatt, J. B. Crawford, and R. H. H. Newton to the *Victory*, additional, for Haslar Hospital; S. L. Harke to the *Chatham;* and J. G. Watkins to the *Impregnable*.

ROYAL NAVAL VOLUNTEER RESERVE.

The following appointments have been notified :—Surgeon Probationers: R. Sandilands to the *Avon;* F. McG. Ferguson to the *Albatross;* A. O. Ross to the *Stour;* A. R. Oram to the *Test;* N. Jennings to the *Waveney;* E. P. Hicks to the *Druid;* and T. R. F. Kerby to the *Minstrel*.

ROYAL ARMY MEDICAL CORPS.

The undermentioned Captains to be Majors:—Dated Feb. 28th: Arthur C. H. Gray, Douglas P. Watson, Thomas S. Dudding, John E. Powell, Osburne Ievers, Robert H. MacNicol, Hugh H. J. Fawcett, Santiago L. Pallant, Charles R. Sylvester-Bradley, Stanley E. Lewis, Gerard A. Kempthorne, James T. McEntire, Norman E. Dunkerton, Patrick J. Hanafin, John D. Richmond, Marmaduke C. Wetherell, Harold C. Hildreth, William MacD. MacDowall, Reginald T. Collins, Thomas J. Wright, and Arthur C. Osburn.

Herbert Clifford Barclay to be temporary Major (dated March 8th).

Temporary Lieutenant Malcolm C. R. Grahame to be temporary Captain (dated April 10th).

The undermentioned are granted temporary rank whilst serving with the Liverpool Merchants Mobile Hospital:—Dated March 25th: Lieutenant-Colonel: Nathan Raw, late Lieutenant-Colonel, Royal Army Medical Corps, Territorial Force. Major: Thomas Caldwell Litler Jones and Major Arthur Augustus Mussen, Royal Army Medical Corps, Territorial Force. Captain: John Hayward and Stanley Raw. Lieutenant: Harold Bowring, John Miller Woodburn Morison, and Henry Wallace Jones.

Temporary Lieutenant-Colonel (Major, Royal Army Medical Corps, Territorial Force) William A. Turner relinquishes his temporary commission (dated March 29th).

Temporary Captain F. Armstrong having ceased to serve with the Welsh Hospital, relinquishes his commission (dated March 31st).

David Llewelyn Williams to be temporary Captain whilst serving with the Sanitary Section of the Welsh Division (dated Jan. 13th).

Captain Robert J. B. Buchanan, from the Half-pay List, is restored to the establishment (dated March 30th).

Emrys Roberts to be temporary Captain whilst serving with the Field Ambulances of the Welsh Division (dated Jan. 29th).

Arthur Meurig Pryce to be temporary Lieutenant whilst serving with the Field Ambulances of the Welsh Division (dated March 4th).

The undermentioned to be temporary Lieutenants:—Dated Nov. 21st, 1914: Stephen Grange Askey, Percival Courtenay Cole, and Ambrose Wilfred Owen. Dated March 8th: James Leonard Octavius Tilley. Dated March 9th: George Stanley Phillips and Martin Ainger Kirton. Dated March 10th: William Mary O'Connor and William Wagner Turner. Dated March 12th: Horace Burcham Binks, Alexander Hugh Davidson, Samuel Kenny McKee, Robert Noel Thomson, and Arthur Canston Freeth. Dated March 14th: John Vassie Buchanan. Dated March 15th: Michael Louis Neylon, Edward Holmes Rainey, Norman Walmesley Steinberg, Henry Harrison Rudolf Bayley, Lionel Walter Kennedy Scargill, Edward Colston Williams, James Hutchison, John Alexander Douglas Radcliffe, George Riddoch, Victor Joseph McAllister, William Wilson Thomson, Lawrence Drew Shaw, and Arthur Thomas Paterson. Dated March 16th: Russell Vyvyan Steele, Sidney Ernest Elphick, Edward John Eedle, Richard Brinsley Hunt, Charles Stuart, Evan Greene, George Robert Lawless, Montague Albert Farr, Norman Douglas Mackay, Ernest Hamilton Kenny, and Hamilton Mathewson. Dated March 17th: John Walker Wood, John Stewart Caldwell, William Morrison, Rowland Hill Scovell, Owen Henry Bowen, Joseph Currie Lorraine, William Wilkie Scott, and Alfred James Anderson Peters. Dated March 19th: Thomas Graham Brown and Robert Slaney.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

Percy Barnard Corbett to be Lieutenant.

The undermentioned Lieutenants are confirmed in their rank:—William B. Jepson and Noel H. W. Saw. Peter MacCallum, Cadet of the Officers Training Corps, to be Lieutenant (on probation).

TERRITORIAL FORCE.

Army Medical Services.

Major G. St. C. Thom, R.A.M.C., vacates the appointment as Deputy Assistant Director of Medical Services, Lowland Division (dated Feb. 21st).

Major Alexander M. McIntosh, from 3rd Lowland Field Ambulance, to be Deputy Assistant Director of Medical Services, Lowland Division (dated Feb. 21st).

Royal Army Medical Corps.

3rd East Anglian Field Ambulance:—Captain Samuel Hughes, from 5th Southern General Hospital, to be Captain (temporary).

2nd Northumbrian Field Ambulance: Herbert Bruce Low (late Captain, 7th Battalion, Durham Light Infantry), to be Captain (temporary).

1st South Western Mounted Brigade Field Ambulance: William Arnold Milner to be Lieutenant.

1st West Lancashire Field Ambulance: Leonard Boole Stott to be Lieutenant.

1st South Midland Field Ambulance: William James Hirst to be Lieutenant.

2nd Welsh Field Ambulance: John Phillip Henry Davies to be Lieutenant.

1st Eastern General Hospital: James Christian Simpson to be Captain, whose services will be available on mobilisation. Robertson Campbell Canney (late Cadet Corporal, London University Contingent, Senior Division, Officers Training Corps) to be Captain, whose services will be available on mobilisation.

1st Southern General Hospital: Arthur Christopher Tibbits to be Lieutenant.

2nd Southern General Hospital: Captain Francis H. Edgeworth to be Major.

1st London (City of London) Sanitary Company: Lionel Watson Hignett to be Lieutenant.

2nd London Sanitary Company: Captain Reginald O. Sibley, from the 4th London General Hospital, to be Captain.

1st London Casualty Clearing Station: Cecil Arthur Robinson to be Lieutenant.

South Midland Casualty Clearing Station: Lieutenant-Colonel William H. Stephen, from 1st South Midland Mounted Brigade Field Ambulance, to be Lieutenant-Colonel.

3rd London General Hospital: Major Arthur W. Mayo Robson, C.V.O., is seconded.

3rd Southern General Hospital: The undermentioned officers are seconded under Paragraph 112, Territorial Force Regulations: Lieutenant-Colonels William T. Freeman and William J. Maurice; Majors George S. Abram, Lansdown M. Guilding, John A. P. Price, and Robert Ritson; Captains Norton B. Clowes, George H. R. Holden, George F. Murrell, Walter B. Secretan, and Fielding Clarke.

2nd London (City of London) General Hospital: Captain Edwin H. Fenwick to be Lieutenant-Colonel (temporary), and is seconded.

Attached to Units other than Medical Units.—Thomas Frankish (late Lieutenant-Colonel, 1st East Lancashire Brigade, Royal Field Artillery), to be Major. To be Lieutenants: James Mathews Heron and Henry William Lance. Lieutenant-Colonel and Honorary Surgeon-Colonel Charles Downing resigns his commission on account of ill-health, and is granted permission to retain his rank and wear the prescribed uniform. Major Robert W. Forrest is placed on Half-pay List on account of ill-health.

DEATHS IN THE SERVICES.

Lieutenant-Colonel William Sandilands Harrison, R.A.M.C., on April 12th, at Haslingden, Lancashire. He became a lieutenant in the Royal Army Medical Corps in 1895, was made a captain in 1898, major in 1906, and was promoted to the rank of lieutenant-colonel last year. He served with the Tirah Expeditionary Force during the operations on the North-West Frontier of India in 1897–8 (medal with clasp). After pursuing research work in Jamaica on tropical diseases he was invalided home, and his death at the early age of 43 years is directly attributable to his investigations.

Deputy Inspector-General Henry L. Crocker, R.N., has been awarded a Greenwich Hospital pension of £50 a year.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

In the 96 English and Welsh towns with populations exceeding 50,000 persons at the last census, 8048 births and 6885 deaths were registered during the week ended Saturday, April 3rd. The annual rate of mortality in these towns, which in the three preceding weeks had been 19·7, 19·3, and 19·8 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of this year, was again 19·8 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these towns averaged 19·6, against 20·6 per 1000 in London. Among the several towns the death-rate in the week under review ranged from 8·2 in Gloucester, 8·9 in Bath, 9·6 in Wimbledon, 10·5 in Darlington, and 10·6 in York, to 27·2 in Middlesbrough, 28·0 in Gateshead, 31·1 in Dudley, 32·4 in West Hartlepool, and 36·1 in Northampton.

The 6885 deaths from all causes were 6 in excess of the number in the previous week, and included 826 which were referred to the principal epidemic diseases, against 739 and 695 in the two preceding weeks. Of these 826 deaths, 495 resulted from measles, 157 from whooping-cough, 77 from infantile diarrhœal diseases, 69 from diphtheria, 16 from scarlet fever, and 12 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·4, or 0·4 per 1000 higher than in the previous week. The deaths attributed to measles, which had been 373, 421, and 397 in the three preceding weeks, rose to 495 in the week under notice, and caused the highest annual death-rates of 3·5 in Coventry, 3·8 in Sheffield, 3·9 in Carlisle, 4·1 in Acton, 4·3 in Merthyr Tydfil, 5·2 in St. Helens, 6·5 in Wolverhampton, 8·6 in Northampton, and 11·3 in West Hartlepool. The deaths referred to whooping-cough, which had been 120, 151, and 127 in the three preceding weeks, rose to 157; the highest death-rates from this cause were 1·3 in Southampton, 1·6 in Middlesbrough, 1·9 in Barnsley, 2·0 in Carlisle, 2·1 in Bootle, 2·5 in Merthyr Tydfil, and 4·0 in Wigan. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 77, 63, and 70 in the three preceding weeks, rose to 77, of which 18 were recorded in London, 8 in Birmingham, 6 in Middlesbrough, and 4 each in Liverpool and Leeds. The deaths attributed to diphtheria, which had been 51, 61, and 58 in the three preceding weeks, rose to 69, and included 16 in London, 4 each in Birmingham, Liverpool, Manchester, and Sheffield, and 3 each in Warrington, Rotherham, and Cardiff. The deaths referred to scarlet fever, which had been 21, 29, and 31 in the three preceding weeks, declined to 16, of which 5 occurred in London, 3 in Salford, and 2 in Oldham. The fatal cases of enteric fever, which had been 15, 14, and 12 in the three preceding weeks, were again 12 in the week under notice, but showed no excess in any particular town.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5036 to 2672 in the 18 preceding weeks, had further fallen to 2543 on Saturday, April 3rd; 253 new cases were admitted during the week, against 275, 289, and 301 in the three preceding weeks. These hospitals also contained 1369 cases of diphtheria, 371 of measles, 46 of enteric fever, 14 of whooping-cough, and 3 of small-pox. The 1849 deaths from all causes in London were 86 fewer than in the previous week, and corresponded to an annual death-rate of 21·3 per 1000. The deaths referred to diseases of the respiratory system, which had been 442, 478, and 481 in the three preceding weeks, fell to 475 in the week under notice, but were 195 above the number registered in the corresponding week of last year. The deaths from influenza numbered 45, against 54, 67, and 65 in the three preceding weeks.

Of the 6885 deaths from all causes in the 96 towns 195 resulted from different forms of violence and 414 were the subject of coroners' inquests, while 1804 occurred in public institutions. The causes of 64, or 0·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Manchester, Leeds, Bradford, Newcastle-on-Tyne, and in 54 other smaller towns. Of the 64 uncertified causes, 14 were registered in Birmingham, 9 in Liverpool, 8 in Gateshead, 5 in Stoke-on-Trent, 4 in Warrington, 3 in Sheffield, and 2 each in Bootle, Darlington, South Shields, and Tynemouth.

In the 96 English and Welsh towns 8710 births and 6922 deaths were registered during the week ended Saturday, April 10th. The annual rate of mortality in these towns, which had been 19·3, 19·8, and 19·8 per 1000 in the three preceding weeks, further rose to 19·9 per 1000 in the week under notice. The annual death-rate last week ranged from 8·7 in Lincoln, 8·9 in East Ham, 9·2 in Ilford, 10·3 in Gloucester, and 10·9 in Swindon, to 27·6 in Rochdale, 28·6 in Carlisle, 29·3 in West Bromwich, 30·1 in Dudley, and 36·0 in Wolverhampton.

The 6922 deaths from all causes were 37 in excess of the number in the previous week, and included 767 which were referred to the principal epidemic diseases, against 695 and 826 in the two preceding weeks. Of these 767 deaths, 452 resulted from measles, 167 from whooping-cough, 67 from infantile diarrhœal diseases, 49 from diphtheria, 25 from scarlet fever, and 7 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·2, or 0·2 per 1000 less than in the previous week. The deaths attributed to measles, which had been 421, 397, and 495 in the three preceding weeks, fell to 452 last week, and caused the highest annual death-rates of 4·0 in Croydon, 4·1 in Smethwick, 4·4 in Sheffield and in Stockton-on-Tees, 5·5 in Walsall, 5·7 in West Hartlepool, 5·9 in Carlisle, 6·0 in West Bromwich, 6·9 in Northampton, and 8·7 in Wolverhampton. The deaths referred to whooping-cough, which had been 151, 127, and 157 in the three preceding weeks, further rose to 167 last week, and included 50 in London, 11 in Wigan, 10 in Liverpool, 6 in Birmingham, 5 each in Sheffield and Merthyr, and 4 each in Bristol, Nottingham, Bradford, and Newcastle-on-Tyne. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 63, 70, and 77 in the three preceding weeks, declined to 67 last week, of which 13 occurred in London and 5 each in Birmingham, Liverpool, and Sheffield, and 4 in Manchester. The deaths attributed to diphtheria, which had been 61, 58, and 69 in the three preceding weeks, fell to 49 last week, and included 11 in London, 4 in Liverpool, and 3 in Northampton. The deaths referred to scarlet fever, which had been 29, 31, and 16 in the three preceding weeks, rose to 25 last week, of which 4 were registered in London, 3 in Sheffield, and 2 each in Nottingham and Cardiff. The fatal cases of enteric fever, which had been 14, 12, and 12 in the three preceding weeks, further fell to 7 last week, but showed no excess in any particular town.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5036 to 2543 in the 19 preceding weeks, had further fallen to 2505 on Saturday last; 275 new cases were admitted during the week, against 289, 301, and 253 in the three preceding weeks. These hospitals also contained on Saturday last 1346 cases of diphtheria, 347 of measles, 57 of enteric fever, 15 of whooping-cough, and 3 of small-pox. The 1826 deaths from all causes in London were 22 fewer than in the previous week, and corresponded to an annual rate of 21·1 per 1000. The deaths referred to diseases of the respiratory system, which had been 478, 481, and 475 in the three preceding weeks, further fell to 466 in the week under notice, but were 247 in excess of the number registered in the corresponding week of last year. The deaths from influenza numbered 46, against 67, 65, and 45 in the three preceding weeks.

Of the 6922 deaths from all causes in the 96 towns, 251 resulted from different forms of violence, and 543 were the subject of coroners' inquests, while 1941 occurred in public institutions. The causes of 66, or 1·0 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Sheffield, Leeds, Bristol, West Ham, Bradford, Newcastle-on-Tyne, and in 63 other smaller towns. Of the 66 uncertified causes, 11 were registered in Birmingham, 10 in Liverpool, 5 in Stoke-on-Trent, 4 in Dudley, and 3 each in Coventry and Gateshead.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1144 births and 995 deaths were registered during the week ended Saturday, April 3rd. The annual rate of mortality in these towns, which had been 20·9, 20·8, and 21·1 per 1000 in the three preceding weeks, further rose to 22·1 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these towns averaged 22·4, against a corresponding rate of 19·6 per 1000 in the large English towns. Among the several towns the death-rate in the week under notice ranged from 11·3 in Motherwell, 15·3 in Kirkcaldy, and 16·2 in Leith, to 23·3 in Edinburgh, 27·1 in Dundee, and 31·1 in Hamilton.

The 995 deaths from all causes exceeded those in the previous week by 47, and included 181 which were referred to the principal epidemic diseases, against 139 and 132 in the two preceding weeks. Of these 181 deaths, 104 resulted from whooping-cough, 45 from measles, 11 from scarlet fever, 10 from infantile diarrhœal diseases, 6 from diphtheria, and 5 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 4·0, against a corresponding rate of 2·4 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had been 87, 88, and 81 in the three preceding weeks, rose to 104 in the week under notice, and included 60 in Glasgow, 19 in Dundee, 5 in Edinburgh, 4 in Hamilton, and 3 each in Leith, Clydebank, and Ayr. The deaths referred to measles, which had been 15, 26, and 21 in the three preceding weeks, rose to 45, and comprised 31 in Glasgow, 8 in Dundee, 3 in Aberdeen, 2 in Edinburgh, and 1 in Perth. The fatal cases of scarlet fever, which had been 13, 11, and 12 in the three preceding weeks, fell to 11, and included 5 in Glasgow and 2 each in Aberdeen and Paisley. The deaths of infants (under 2 years) attributed to diarrhœa and enteritis, which had been 5, 6, and 10 in the three preceding weeks, were again 10 in the week under review, of which 5 occurred in Glasgow and 2 in Aberdeen. The deaths referred to diphtheria, which had declined from 15 to 7 in the four preceding weeks, further fell to 6, and comprised 3 in Edinburgh, 2 in Glasgow, and 1 in Paisley. The 5 fatal cases of enteric fever occurred in Glasgow.

The deaths referred to diseases of the respiratory system, which had declined from 264 to 186 in the four preceding weeks, further fell to 162 in the week under notice, and were 4 below the number in the corresponding week of last year. The deaths attributed to violence numbered 21, against 36 and 34 in the two preceding weeks.

In the 16 largest Scotch towns 1291 births and 934 deaths were registered during the week ended Saturday, April 10th. The annual rate of mortality in these towns, which had been 20·8, 21·1, and 22·1 per 1000 in the three preceding weeks, fell to 20·8 per 1000 in the week under notice. Among the several towns the death-rate ranged from 7·6 in Falkirk, 11·8 in Coatbridge, and 12·9 in Clydebank, to 22·6 in Glasgow, 23·8 in Dundee, and 34·7 in Greenock.

The 934 deaths from all causes were 61 fewer than in the previous week, and included 154 which were referred to the principal epidemic diseases, against 132 and 181 in the two preceding weeks. Of these 154 deaths, 75 resulted from whooping-cough, 41 from measles, 18 from infantile diarrhœal diseases, 11 from diphtheria, 6 from scarlet fever, and 3 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 3·4, against 2·2 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had been 88, 81, and 104 in the three preceding weeks, fell to 75 last week, of which 37 were recorded in Glasgow, 11 in Dundee, 9 in Edinburgh, 6 in Greenock, and 5 in Leith. The deaths referred to measles, which had been 26, 21, and 45 in the three preceding weeks, fell to 41 last week, and comprised 30 in Glasgow, 8 in Dundee, and 3 in Aberdeen. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 6, 10, and 10 in the three preceding weeks, further rose to 18 last week, and included 7 in Glasgow and 3 each in Dundee and Kilmarnock. The deaths attributed to diphtheria, which had declined from 15 to 6 in the five preceding weeks, rose to 11 last week, of which 5 occurred in Glasgow and 3 in Edinburgh. The deaths referred to scarlet fever, which had been 11, 12, and 11 in the three preceding weeks, declined to 6 last week, and included 4 in Glasgow. Of the 3 fatal cases of enteric fever, 2 occurred in Glasgow and 1 in Kirkcaldy.

The deaths referred to diseases of the respiratory system, which had declined from 264 to 162 in the five preceding weeks, rose to 182 in the week under notice, and were 45 above the number registered in the corresponding week of last year. The deaths attributed to violence numbered 32, against numbers declining from 36 to 21 in the three preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,212,380 persons at the middle of this year, 597 births and 533 deaths were registered during the week ended Saturday, April 3rd. The annual rate of mortality in these towns, which had declined from 27·6 to 23·9 per 1000 in the five preceding weeks, further fell to 22·9 per 1000 in the week under notice. During the 13 weeks of the quarter just ended the mean annual death-rate in these towns averaged 25·4, against corresponding rates of 19·6 and 22·4 per 1000 in the English and Scotch towns respectively. The death-rate during the week under review was equal to 22·9 in Dublin (against 21·3 in London and 23·1 in Glasgow), 23·3 in Belfast, 28·6 in Cork, 10·1 in Londonderry, 13·5 in Limerick, and 26·6 in Waterford, while in the 21 smaller towns the mean death-rate was 23·8 per 1000.

The 533 deaths from all causes were 22 fewer than the number in the previous week, and included 37 which were referred to the principal epidemic diseases, against 36 and 47 in the two preceding weeks. Of these 37 deaths, 13 resulted from whooping-cough, 11 from infantile diarrhœal diseases, 7 from measles, and 3 each from scarlet fever and enteric fever, but not one from diphtheria or from small-pox. The annual death-rate from these diseases was equal to 1·6, against corresponding rates of 2·4 and 4·0 per 1000 in the English and Scotch towns respectively. The deaths attributed to whooping-cough, which had increased from 10 to 16 in the four preceding weeks, fell to 13 in the week under notice, and comprised 10 in Dublin and 3 in Belfast. The deaths of infants (under 2 years) referred to diarrhœa and enteritis, which had been 14, 4, and 11 in the three preceding weeks, were again 11, and included 4 each in Dublin and Belfast. The fatal cases of measles, which had been 8, 8, and 12 in the three preceding weeks, fell to 7, and comprised 4 in Belfast and 3 in Portadown. The 3 deaths attributed to scarlet fever, of which 2 occurred in Dublin and 1 in Clonmel, were slightly below the average in the earlier weeks of the quarter. Of the 3 deaths referred to enteric fever 2 were recorded in Cork and 1 in Dublin. In addition to the above deaths a fatal case of typhus was registered in Dublin.

The deaths referred to diseases of the respiratory system, which had declined from 188 to 145 in the four preceding weeks, further fell to 121 in the week under notice. Of the 533 deaths from all causes, 161, or 30 per cent., occurred in public institutions, and 5 resulted from various forms of violence. The causes of 28, or 5·3 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the English towns the proportion of uncertified causes did not exceed 0·9 per cent.

In the 27 town districts of Ireland 633 births and 553 deaths were registered during the week ended Saturday, April 10th. The annual rate of mortality in these towns, which had steadily declined from 27·6 to 22·9 per 1000 in the six preceding weeks, rose to 23·8 per 1000 in the week under notice. The death-rate was equal to 26·1 in Dublin (against 21·1 in London and 22·6 in Glasgow), 21·1 in Belfast, 19·7 in Cork, 15·2 in Londonderry, 36·6 in Limerick, and 41·8 in Waterford, while in the 21 smaller towns the mean rate was 22·9 per 1000.

The 553 deaths from all causes were 20 in excess of the number in the previous week, and included 40 which were referred to the principal epidemic diseases, against 47 and 37 in the two preceding weeks. Of these 40 deaths, 16 resulted from measles, 15 from whooping-cough, and 3 each from enteric fever, scarlet fever, and infantile diarrhœal diseases, but not one from diphtheria or from small-pox. The mean annual rate from these diseases was equal to 1·7, against corresponding rates of 2·2 and

3·4 per 1000 in the English and Scotch towns respectively. The deaths referred to measles, which had been 8, 12, and 7 in the three preceding weeks, rose to 16 last week, and included 6 each in Belfast and Coleraine and 4 in Portadown. The deaths attributed to whooping-cough, which had been 14, 16, and 13 in the three preceding weeks, rose to 15 last week, and comprised 9 in Dublin, 5 in Belfast, and 1 in Cork. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 4, 11, and 11 in the three preceding weeks, declined to 3 last week. Of the 3 deaths from scarlet fever, 2 occurred in Waterford and 1 in Newtownards. The 3 fatal cases of enteric fever were registered in Dublin.

The deaths referred to diseases of the respiratory system, which had declined from 188 to 121 in the five preceding weeks, rose to 158 in the week under notice. Of the 553 deaths from all causes, 151, or 37 per cent., occurred in public institutions, and 7 resulted from various forms of violence. The causes of 17, or 3·1 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the English towns the proportion of uncertified causes did not exceed 1·0 per cent.

A "LINEN LEAGUE."—At a meeting held at the South Devon and East Cornwall Hospital on April 9th, under the presidency of Sir Henry Lopes, it was decided to form a "linen league" in connexion with the institution. The league will supply linen, quilts, bed-clothing, &c., for the use of the patients. It is hoped that this will be the means of saving the hospital £200 per annum, which is the sum of money at present spent on these articles.

ROYAL MEDICAL BENEVOLENT FUND.—The following is a further summary of cases recently relieved by the Fund:—

Daughter, aged 49, of F.R.C.S. Eng. who practised at Bigglesdale. Suffering from epilepsy and has a chronic gastric ulcer. Only income £21 per year from another charity. Relieved 16 times, £141. Voted £12 in 12 instalments.—Widow, aged 77, of M.D. Glasg. who practised at Bournemouth. Lives in own house, but daughter who is a musician and helped to keep the home unable to obtain engagements since the war, and two sons, artists, unable to help. Previous relief 11 times, £62. Voted £5 and recommended for an annuity.—Widow, aged 76, of M.R.C.S. Eng. who practised at Islington. Health bad and failing eyesight. Only income old age pension. One son, a commercial traveller, married, with family, unable to help. Relieved once, £18. Voted £18 in 12 instalments.—Widow, aged 57, of M.D. Edin. who practised at Wetheral. Tries to earn a little by taking boarders, but has not been successful of late. Suffering from chronic rheumatism. Only son abroad and only able to help slightly. Previous help 8 times, £96. Voted £12 in 12 instalments.—Widow, aged 67, of M.R.C.S. Eng. who practised in London. Suffering from malignant growth in left breast and quite unable to do anything. Five children, but only three of the daughters are able to help very slightly. Previous relief 16 times, £183. Voted £12 in two instalments.

CEREBRO-SPINAL MENINGITIS.

To the Editor of THE LANCET.

SIR,—In his interesting paper on meningococci in peripheral blood in THE LANCET of April 10th Dr. A. C. Coles asks if the discovery of the germ in blood films made from peripheral blood is a practical method of diagnosis, or are the meningococci only to be found in the septicæmic type of the disease?

Personally, I believe this to be the method of diagnosis which will shortly be widely adopted. I found the germ in 80 consecutive cases,[1] and found it more readily in this manner than from the throat, &c. In some cases I failed to grow any diplococcus from any source, including the cerebro-spinal fluid, though the patient died with typical symptoms, and blood films had shown diplococci during life, and films made from the cerebro-spinal fluid showed intracellular diplococci after death.

But we have to prove that the germ we find in peripheral blood films is the germ which causes the disease, for this is not yet admitted by all, particularly in slight cases. In blood the meningococci I have seen often have a capsule. I have not seen this fact mentioned. As Dr. Coles points out, there is a strong resemblance to the gonococcus, and recognising the possibility of mutation in this germ as in others, it would appear desirable that further investigations should at once be made. The presence of the gonococcus in the blood in sufficiently large numbers to be found in blood films is, to say the least, not a common event, and the symptoms of the two diseases are sufficiently unlike to make confusion between the two unlikely. The pneumococcus may be put out of court by the fact that it is strongly Gram-positive and the meningococci are not.

The micrococcus catarrhalis is not mentioned by Dr. W. d'Este Emery[2] as being found in the blood, so I think we may take it that it is not a frequent habitant. The diplococci which remain are the meningococci, and it will be interesting to ascertain the exact characters of the organism found, particularly whether the diplococci described by Weichselbaum, Jaeger, and others owe their differences to environmental conditions. But the first theorems needing proof are (1) diplococci are to be found in the peripheral blood in practically all cases, and (2) they are the same diplococci as those found in the meninges.

But I would wish to give one word of warning as the result of my own failures to grow the germ in some cases in which I found it in the blood. It is not easy to grow unless special care is taken, as is shown by the various reports already published, and it *is* commonly easy to detect in the blood. Hence it is important that this question of identity be settled as soon as possible, so that the simpler method of diagnosis may be utilised if it is shown to be adequate. Anyone who has frequently made cultures from blood will agree that a few drops are not enough. Even where the germ can be seen in blood films 2–5 c.c. are needed. Hence, if mere examination of blood films is sufficient, it is important that we know the fact as soon as possible.

---

[2] Clinical Bacteriology and Hæmatology, d'Este Emery, p. 158.

I am, Sir, yours faithfully,
Colwall, April 12th, 1915. MARY H. WILLIAMS.

To the Editor of THE LANCET.

SIR,—The very interesting report of a case of the above disease sent by Dr. Alfred C. Coles to THE LANCET of April 10th will, I hope, be followed by other reports where early blood examinations have been made. If the meningococci are to be generally found in the blood it will be useful for early diagnosis, especially for practitioners in the country who may not have, or be able to procure, the necessary instrument for lumbar puncture. In the case of the blood being found infected it will give us an opportunity to try the soamin treatment described by Dr. George Low in the *British Medical Journal* of Feb. 27th last, and also used by Mr. E. Norman Butler in British East Africa and described in THE LANCET of April 3rd.

In a case I had recently the symptoms tallied with those of Dr. A. D. Edwards's case as quoted by Dr. Coles—viz., intense pain in the lumbar region and vomiting and *no* head retraction—I notice the early symptoms of the African native cases were intense headache and head retraction. In my case meningococci were found after lumbar puncture, but blood was not examined. After consultation with Dr. Hyla Greves, of Bournemouth, soamin was tried and seemed to benefit the patient for a fortnight, but the case then got rapidly worse and Flexner's serum was used, though too late, as the patient died on the twentieth day after onset. I hope statistics will soon be published showing the mortality rate of the disease, where serum has been used and where not.

I am, Sir, yours faithfully,
Christchurch, Hants, April 11th, 1915. W. MOSS BRISTOW.

ANGINA PECTORIS.

To the Editor of THE LANCET.

SIR,—I am much interested in the letter of Dr. Edgar Lea on a case of angina pectoris, in your issue of April 10th. The case was one of syphilitic aortitis with angina, and needs no particular "segmental" or other "neurosis" to explain it. Dr. Lea's able letter gives precisely the data wanted in such cases. But I wish to thank him especially for his careful observations concerning tender points. Their physiological interest is great, but, like Dr. Lea, I have found them too fugitive and inconstant for clinical use; and this opinion I have diffidently ventured to state already in my book on arterial disease, which now—after long delays due to the war—will, I trust, soon be published.

I am, Sir, yours faithfully,
Cambridge, April 10th, 1915. CLIFFORD ALLBUTT.

HEALTH RESORTS FOR CONVALESCENCE AND SICK LEAVE IN THE ARMY.

To the Editor of THE LANCET.

SIR,—You have described in a leading article in the last issue of THE LANCET with unanswerable force the hiatus that begins after hospital treatment, and ends either in restoration to health or in chronic disability. It is to be feared that this period of convalescence is often unnecessarily painful and prolonged, and that, indeed, it frequently fails of its effects for want of continued medical care and supervision. Many of the excellent convalescent homes abundantly provide for an uncomplicated recovery, but, as you suggest, there are a very large number of cases in which a continuance of special care and treatment is needful.

Experience has shown that spas and other health resorts are the proper places for these cases. The treatment at health resorts of military cases has been amply justified already in this country, although, happily, on a comparatively small scale. We need only refer to such common conditions as painful wounds, post-operative cases, nervous disorders from shock and injury, rheumatism, tachycardia, &c. For the very large numbers now in contemplation special arrangements are of course requisite, but there is no lack of willing service at the health resorts, and all their resources are freely offered for wounded and invalid soldiers.

A committee of the Council of the Section of Balneology and Climatology of the Royal Society of Medicine has been engaged in collating the necessary information and supplying it to the military authorities. They have prepared a short pamphlet which includes: (1) a summary of the medical and surgical maladies most commonly met with in the military hospitals, for which spa treatment at a health resort is indicated; and (2) a list of the British spas, as well as other bathing establishments, with the factors influencing the preference for one or another in the treatment of such maladies.

It is the aim of the committee in association with local committees and representatives throughout the country to fill the hiatus to which you have referred by organising a scientific after-treatment at our many valuable health stations. They also have in hand a proposal for furnishing to the War Office returns of the accommodation available, both for men and officers.

The practical carrying out of such a work on a large scale naturally presents some difficulties. To one of these you refer. Medical men, without, at all events, temporary military rank, are often at a loss when in charge of military cases. There is also the larger difficulty how to provide an efficient and scientific distribution of the large numbers of cases leaving the great hospitals, so that each man may be sent to the locality where he will receive the greatest benefit. These and other problems present, however, no insuperable difficulties. They are mainly questions of machinery. The great and encouraging fact is the willingness of all concerned to do their part.

We are, Sir, yours faithfully,
R. FORTESCUE FOX,
April 11th, 1915. J. CAMPBELL MCCLURE.

"THE MINOR HORRORS OF WAR."

To the Editor of THE LANCET.

SIR,—Although the first edition of my little book on the above subject was a large one, a second edition is already being called for.

As I am anxious to make the book as useful as possible, I should be grateful if any medical man who has had actual experience in dealing with *Pediculus vestimenti* and *Pediculus capitis*, and who knows of remedies other than those mentioned in the first edition, would communicate with me at the address given below.

I am, Sir, yours faithfully,
A. E. SHIPLEY.
Christ's College Lodge, Cambridge, April 12th, 1915.

PROBATIONERS AND WAR HOSPITALS.

To the Editor of THE LANCET.

SIR,—I beg to suggest that all probationers having had three months' ward training in the general hospitals be allowed to serve for three or six months in the military hospitals, such time counting as part of the three or the four years' training, as the case may be. The universities and examining boards allow students holding dresserships in the military hospitals to count the time as part of their clinical instruction. The adoption of the above suggestion with regard to nurses brings the two branches of the profession into line, and while the service would prove of great advantage to the sick and wounded, the experience gained by the probationers must add to their future efficiency.

I am, Sir, yours faithfully,

April 12th, 1915. SURGEON.

THE DEARTH OF DOCTORS.

To the Editor of THE LANCET.

SIR,—Dr. William Bruce's letter in your issue of to-day's date is very difficult to understand. Men with four years' training at the hospitals at present have been brought up on a system that would render them very inefficient practitioners if qualified out of hand. Their curriculum, as in the old days, is not devised for it. They would in some cases be a source of grave danger. Nobody should know this better than a one-time member of the General Medical Council. Again, if we *de novo* revert to the old four years' system from this on we may get a large crop, but, I fear, very many tares. Medical science has advanced too far for even the elements to be learned by the average man in five years. After a good training as house surgeon or the like, he may have a working knowledge but no more. Now why revert to a four years' course when the war cannot last so long? Men are being qualified fairly rapidly; thousands of other men are abroad, and very many thousands fit and well at home. Most of these will be ready for work when the war is over. The plan outlined in your leading article seems not only the best but the sole plan that can meet the situation.

I am, Sir, yours faithfully,

April 10th, 1915. X. Y. Z.

To the Editor of THE LANCET.

SIR,—With regard to the letter by Dr. W. Bruce on this subject in THE LANCET of April 10th, may I point out how in one or two directions the shortage of doctors for the army might be relieved? 1. A certain number of qualified men are serving as combatants; they should be transferred to the Royal Army Medical Corps. 2. The Reserve Corps of Territorials, and those units who have not volunteered for service abroad, absorb a considerable number of men whose time is by no means fully occupied, and whose duties could be easily undertaken by part-time civilians. 3. The services of a number of experienced men, who are not too old at 40 or even 50, could be obtained to do the work at base hospitals either in France or at home, setting free a corresponding number of younger men for service in the field.

In this, as in so many other directions, we are hampered by the absence of compulsory military service by which every man could be made to do the national work for which he was most fitted.

I am, Sir, yours faithfully,

TEMPORARY LIEUTENANT, R.A.M.C. (T.).

April 12th, 1915.

Obituary.

PROFESSOR FRIEDRICH LOEFFLER.

THE death is announced of Professor Friedrich Loeffler, the eminent bacteriologist. He was born at Frankfort-on-the-Oder in 1852, and was educated in the Universities of Würzburg and Berlin. In 1888 he was appointed professor and director of the Hygienic Institute at the University of Greifswald, and in 1895 he was elected a member of the Imperial Institute, when, in conjunction with Koch and Gaffky, he pursued some investigations in regard to disinfection by means of steam.

His researches carried him into various paths of bacteriology, but it was in reference to the causal organism of diphtheria that he was best known. Klebs in 1883 had described a bacillus which he had observed in diphtheritic membranes, but Loeffler was the first who succeeded in cultivating it in artificial media, and in producing in animals by means of inoculations distinct lesions which resembled diphtheria. He had made a careful study of the use of aniline dyes in staining bacteria. The solution known as "Loeffler's methylene blue" is largely employed, and is particularly suitable for the demonstration of the diphtheria bacillus, as it brings out well the metachromatism of the granules in the bacilli. His researches in diphtheria as occurring in animals and birds were also valuable. He succeeded in producing membranous inflammation in guinea-pigs by vigorously inoculating the vaginal mucosa, and in rabbits by treating the conjunctiva or tracheal mucous membrane in a similar manner. He further investigated the disease as occurring in calves and pigeons. Amongst other morbid conditions which he investigated may be mentioned the "red murrain" of pigs, which until then had been classed with swine fever.

Professor Loeffler as a pioneer will be placed amongst the foremost of German scientists. The results of his researches, both directly and indirectly, as leading up to the work of other observers (as, for instance, the introduction of the antitoxin treatment of diphtheria), have proved of the highest value to mankind, whilst the manner in which his investigations were conducted has formed a firm and instructive basis for other bacteriologists.

HENRY LEWIS JONES, M.D. CANTAB., F.R.C.P. LOND.,

CONSULTING MEDICAL OFFICER TO THE ELECTRICAL DEPARTMENT AT ST. BARTHOLOMEW'S HOSPITAL.

WE announced last week the death of Dr. Henry Lewis Jones, consulting medical officer to the electrical department at St. Bartholomew's Hospital, which took place on April 4th, at his residence in Harley-street. He had for a long period been in bad health. The disease to which he ultimately succumbed was at first very obscure in its manifestations, and an operation performed nearly two years ago was for a time successful, so that until September of last year he was able to carry on his extensive practice. But it was recognised that the improvement might be only temporary, and the death of his only son, who went down in H.M.S. *Hawke*, proved a shock from which he never really rallied. From that day he steadily lost ground, and the end was expected.

Henry Lewis Jones, who was born in 1857, the son of a naval chaplain, was educated at Shrewsbury School and Caius College, Cambridge, which college he entered in 1876 as a senior science scholar. He graduated with honours in the Natural Science Tripos and found time also to stroke with success one of his college boats at a time when Caius rowing was particularly good. From Cambridge he went to St. Bartholomew's Hospital, where, having held all the usual appointments, he particularly devoted his attention to the use of electricity in medicine, a branch of therapeutics which 30 years ago was only threatening the position which it has since reached. He was elected physician in charge of the electrical department at St. Bartholomew's Hospital, and throughout his association with that hospital he proved himself the effective pioneer of his subject in this country. He was thoroughly practical as well as really learned, he had the power of explaining himself, and was quick to encourage ability in others. He could teach verbally, and write clearly. His book on "Medical Electricity," which is now in its sixth edition, fully deserves the success which it has attained, while his more recent small work on ionic medication was the first attempt to explain to the medical profession generally the principles of the method, and to give an account of the clinical results to be derived from its employment. The writings of Lewis Jones, in fact, have done more than any others to give medical electricity the position which it now holds in this country, and it was largely due to him that ionic medication made strides in professional favour. In his treatises he avoided theoretical discussions as far as possible, while the clinical records which accompanied the work on ionic medication were nearly all concerned with lesions of a superficial character; and this was characteristic of the author's thoroughness and honesty. He was determined not to exploit a good thing by using it wrongly, and to lead no one else into mistaken enthusiasm; indeed, he protested against the way in which, for example, subjects of polyarticular arthritis have been subjected often by unqualified persons to so-called ionic medication. His position was recognised by Government, who asked him to act as official delegate at the International Congress of Physiotherapy at Liége in 1905, and at a similar Congress in Paris five years later, while in 1913 he was President of the British Electro-Therapeutic Society.

Henry Lewis Jones was scientific to his fingertips and absolutely practical. He was extremely shrewd in his judgments, but quite broad-minded in his attitudes. He was very hard-working, but found time to enjoy life. In him we have lost one of the best type of practising physicians, and many personal friends will regret him.

He married in 1896 the eldest daughter of Count H. H. Platen-Hallermund, by whom he had one son, whose sad death has been mentioned.

WILLIAM ARTHUR BRAILEY, M.A., M.D.CANTAB.,

CONSULTING OPHTHALMIC SURGEON TO GUY'S HOSPITAL.

WE regret to announce the death of Dr. William Arthur Brailey, the well-known ophthalmologist, which occurred on April 8th, in his seventieth year, at 11, Old Burlington-street, W.

Dr. Brailey was born at Uttoxeter in 1845, the only boy in a family of seven. He was educated at Woodhouse Grove School and passed the London matriculation at the age of 16 years with first-class honours. He entered at Guy's Hospital, but his health proving unequal to the work, he migrated to Cambridge, where his father, the Rev. William Brailey, a Wesleyan minister, then resided. His health improving, young Brailey was fortunate enough to obtain an open scholarship at Downing College. In 1866 he took the B.A. London with the exhibition in biology, and in 1867 was in the first class in the Cambridge Natural Science Tripos. A few years later (1871) he graduated in medicine at Cambridge, and in the same year was elected a Fellow of Downing College. He soon returned to Guy's Hospital, but in October, 1873, married and went into general practice. After something less than a year's general practice at Witham, Essex, Brailey returned to London and took up work at the Moorfields Eye Hospital, where he formed a friendship with Sir William Bowman, which ended only with the latter's death. He became registrar and curator at the Moorfields Hospital, and was also appointed lecturer on comparative anatomy at Guy's Hospital. At a somewhat later period, when Mr. Bader relinquished the ophthalmic surgeoncy at Guy's Hospital, he was succeeded by Mr. Charles Higgens, and Dr. Brailey was appointed assistant ophthalmic surgeon. That appointment he held for many years, until, indeed, the statutory age of 60, when he was appointed consulting ophthalmic surgeon to the hospital.

Dr. Brailey was Hunterian professor at the Royal College of Surgeons of England in 1885–86. He took a very prominent part, with Bowman, Hutchinson, Nettleship, and others, in founding the Ophthalmological Society in 1880, and at various times since filled the several offices of vice-president, secretary, and councillor. During the earlier part of its existence he made many notable contributions to its Transactions. In 1890 he was awarded (jointly) the Middlemore prize of the British Medical Association, and later he received the welcome distinction of an honorary Fellowship at his old college.

Dr. Brailey leaves a widow, Agnes, daughter of Mr. John Robertson, and two sons, both members of the medical profession, who are serving their country, one in the navy and the other in the army.

The funeral took place at Warbleton.

BRISTOL EYE DISPENSARY.—At the annual meeting of this dispensary held recently the medical and financial reports were found to be satisfactory. The committee stated that Mr. E. H. E. Stack, who relinquished the surgeoncy of the Eye Dispensary when he was made full surgeon at the Bristol Royal Infirmary, had been re-elected surgeon to the Eye Dispensary, his position of ophthalmic surgeon at the infirmary allowing him to take both appointments.

MEDICAL SICKNESS, ANNUITY, AND LIFE ASSURANCE SOCIETY.—The thirty-second annual meeting of this society was held at the offices in High Holborn, London, W.C., on March 30th. The President, Dr. F. de Havilland Hall, having declared the chairman, vice-chairman, and treasurers re-elected, called on Dr. F. J. Allan to preside. Dr. Allan declared the remaining members of the committee duly elected. The chairman announced that over 300 members of the society were serving in the various forces of the country. The society had had a very successful year. There had been 276 new proposals, and the total membership at the end of the year was 3255. The gross premiums received in the Sickness Fund amounted to £24,190, while £15,931 had been paid in claims. The funds now exceeded £266,500. After some discussion the report and audited accounts were unanimously adopted.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE Fund continues to receive solid support. A letter which has reached the treasurer from Dr. D. Colquhoun, of Dunedin, explains an anonymous contribution of £300 whose receipt was announced on Feb. 27th. The sum was subscribed by doctors, chemists, nurses, and the public of Otago, New Zealand, and was received by the Fund in response to a cable to Lloyds Bank. Such support from New Zealand is particularly gratifying, while we learn from Dr. Colquhoun's letter that he hopes to add further to this handsome contribution, as subscriptions are still coming in to him.

THE WEEK'S SUBSCRIPTIONS.

The subscriptions received by Dr. Des Vœux up to Tuesday evening last, in addition to those previously acknowledged, and not including money collected by the Scottish and Irish Funds, are as follows:—

	£	s.	d.
Birmingham Local Committee (per Dr. Robt. Saundby, Hon. Sec.) (fourteenth donation, total £375 10*s.* 3*d.*)—

Captain R. D. MacGregor, I.M.S. ...	5	0	0
Dr. Craven Moore	5	5	0

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd. £10,012 had passed into the treasurer's hands by Tuesday last, the sum not including the Scottish and Irish Funds.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge the receipt of surgical instruments kindly contributed by Professor Shennan, Aberdeen University; Mr. Horatio P. Symonds, Oxford (per Professor Thomson); Anonymous, Bristol; and Dr. Daniel, Hull (per the Voluntary Aid Committee).

THE UNIVERSITY CHAIR OF PHYSIOLOGY AT ST. BARTHOLOMEW'S HOSPITAL MEDICAL SCHOOL.—Applications for this chair must be received by the academic registrar, University of London, South Kensington, S.W., not later than the first post on May 3rd. Twelve copies of the application must be sent together with the names of not more than three references, but testimonials are not required. The salary is £600 a year.

The War.

THE BATTLE OF NEUVE CHAPELLE: SIR JOHN FRENCH'S DISPATCH.

Sir John French's dispatch, dated April 5th, which was brought to London by H.R.H. the Prince of Wales, contains a warm commendation of the work of the Royal Army Medical Corps and of the Army Medical Service. The following extract from the dispatch will be read with gratification by all members of the medical profession:—

Health of the Army.

Since the date of my last report the general health of the army has been excellent; enteric has decreased, and there has been no recurrence on any appreciable scale of the "foot" trouble which appeared so threatening in December and January. These results are due to the skill and energy which have characterised in a marked degree the work of the Royal Army Medical Corps throughout the campaign, under the able supervision of Surgeon-General T. J. O'Donnell, D.S.O., Deputy Director-General, Medical Services. But much credit is also due to divisional, brigade, regimental, and company commanders for the close supervision which has been kept over the health of their men by seeing that the precautions laid down for the troops before entering and after leaving the trenches are duly observed, and by the establishment and efficient maintenance of bathing-places and wash-houses, and by the ingenious means universally employed throughout the forces to maintain the cleanliness of the men, having regard both to their bodies and their clothing. I have inspected most of these houses and establishments and consider them models of careful organisation and supervision. I would particularly comment upon the energy displayed by the Royal Army Medical Corps in the scientific efforts they have made to discover and check disease in its earliest stages by a system of experimental research, which I think has never before been so fully developed in the field. In this work they have been ably assisted by those distinguished members of the medical profession who are now employed as military medical officers, and whose invaluable services I gratefully acknowledge. The actual strength of the force in the field has been increased, and the health of the troops improved by a system of "convalescent" hospitals. In these establishments slight wounds and minor ailments are treated, and men requiring attention and rest are received. By these means efficient soldiers, whose services would otherwise be lost for a long time, are kept in the country, whilst a large number of men are given immediate relief and rest when they require it without removing them from the area of operations. This adds materially to the fighting efficiency of the Forces.

Army Medical Service and Hospitals.

The principal convalescent hospital is at St. Omer. It was started and organised by Colonel A. F. L. Bate, Army Medical Service, whose zeal, energy, and organising power have rendered it a model hospital of its kind, and this example has materially assisted in the efficient organisation of similar smaller establishments at every Divisional Headquarters.

I have already commented upon the number and severity of the casualties in action which have occurred in the period under report. Here once again I have to draw attention to the excellent work done by Surgeon-General O'Donnell and his officers. No organisation could excel the efficiency of the arrangements—whether in regard to time, space, care and comfort, or transport—which are made for the speedy evacuation of the wounded.

THE WAR AND MEDICAL RECIPROCITY WITH CANADA.

Since the meeting of the Executive Committee of the General Medical Council of Feb. 22nd, 1915, it has been learnt unofficially that a Bill to Amend the Ontario Medical Act and to provide for the registration in Ontario of Medical Practitioners qualified in the United Kingdom has been introduced in the Provincial Legislature by the Attorney-General. The progress of the measure has not yet been announced. Movements towards the establishment of reciprocity have also been taken by other Provinces. On March 24th, 1915, a cable was received from the College of Physicians and Surgeons of the Province of British Columbia stating that their Medical Council had passed a resolution authorising reciprocal arrangements with the United Kingdom. This was confirmed in a letter written on the next day by their Registrar, in which the following phrases show how exactly the situation is being understood in the Dominion:—

> It has been felt for some time that in view of the present conditions, brought on largely by the war, there ought to be reciprocity between this country and Great Britain in order that there may be no question as to the standing of our men serving in Britain or on the continent. It was felt, further, that this was a very fitting time, when every part of the empire is trying to do its best to assist, to bring this matter to a conclusion, and our desire was accordingly cabled to you. It will, of course, be necessary to pass an amendment to our Medical Act. I saw the Attorney General of this Province last night, and he gave me the assurance of his Government that this would be done."

Further, on April 4th, 1915, a cable was received by the General Medical Council from the Registrar of the College of Physicians and Surgeons of the Province of Saskatchewan stating that their Medical Council desired reciprocity, and requesting the General Medical Council of Great Britain to outline procedure. This was at once done, and the much-desired medical reciprocity between Canada and the United Kingdom is now approaching accomplishment, owing to the activity of the General Medical Council and the patriotic sense of Canada.

THE CASUALTY LIST.

Captain D. M. C. Church, I.M.S., is reported as having been wounded in the recent fighting with the Turks in Mesopotamia.

THE COÖPERATION OF CIVIL AND MILITARY AUTHORITIES IN SANITARY MATTERS.

A circular upon this important subject, issued by the Local Government Board this week to county councils, sanitary authorities, port sanitary authorities, and medical officers of health, begins by publishing the gratifying letter from the Assistant Secretary of the Army Council to the Local Government Board which will be found on p. 819 of this issue of THE LANCET.

The circular of the Board cordially endorses the expression of appreciation of the Army Council, and hopes that the assistance which has been rendered will be continued and extended, as "changes in the number or personnel of troops in the area will frequently call for immediate reconsideration or modification of existing arrangements."

The Board take the opportunity of this circular to refer to matters which, in their opinion, it is desirable that local authorities and their officers should give special attention to. The circular runs as follows:—

> *District councils and district medical officers of health.*—Attention is particularly drawn to paragraph (1) on the second page of the Board's Circular (No. 1) as to the duty of district medical officers of health to inquire for and bring at once to the notice of the sanitary authority any conditions in which sanitary services can be rendered by the authority to the military population, and also to the importance of prompt action by the authority on receipt of such reports.

In respect of charges for such services the Board would again insist on the necessity that no urgent sanitary work should be postponed for consideration of the items which may be the subject of charges to the military authorities. For the guidance of sanitary authorities they have included among the appended documents a letter from the Army Council of 31st October, 1914 (No. 3), as to the principles of payment from army funds of charges by local authorities for increased expenditure on sanitary services rendered to troops. The question of payment for professional services of medical officers of health, inspectors of nuisances, &c., is referred to in paragraph 6 (*b*) of that letter. In this instance also the Board consider that the Council should not, pending the adjustment of any application which they may make for reimbursement from army funds, delay the payment to these officers of such sums as may be necessary to recoup them for additional time or special expenses of travelling incurred in the inspections and inquiries, which are essential if the desired coöperation is to be effectively established and continued. The Board will be glad to advise the Council in any case of difficulty arising in these matters.

The attention of district medical officers of health is then directed to the following:—

County councils and county medical officers of health.—The Board and the Army Council attach much importance to the work which has already been done by county medical officers of health in assisting the military authorities in the provision or "pooling" of isolation hospital accommodation, or of arrangements for disinfection within the county, the investigation of infectious disease, the protection of water-supplies, and like matters, and they are desirous that this work should be continued and amplified. With this object the county medical officer of health should obtain from the district medical officer of health each week information (*a*) of the occurrence of any military cases of infectious disease which have come to his knowledge in the district, and (*b*) of any new movements of troops into or out of the district which are known to him. District medical officers of health should give to the county officer any information as to the camps or billeted troops which will assist the latter officer to determine where his assistance may be most needed, and where visits of inspection by him are desirable. It is important that the county medical of health should visit (wherever practicable in conjunction with or after communication with the district medical officer of health) any large camps or important billeting centres. The Board would be glad to receive copies, at the time they are made, of any representations which the county medical officer of health considers it necessary to make, separately or jointly with the district medical officer of health, to the military authorities (No. 1, p. 10), or to sanitary authorities in the county.

Arrangements for bacteriological examinations of contact cases of cerebro-spinal meningitis.—In connexion with the prevalence of cerebro-spinal meningitis in the civil population, some councils, on the advice of their medical officer of health, have already made arrangements for the visits of a bacteriologist to any affected area, and for laboratory examination of material obtained from the contacts of cases of cerebro-spinal meningitis. The Board consider this action of much utility at the present time, alike in the interests of the civil and of the military population, and they trust that it will be actively pursued and extended wherever necessary. Corresponding arrangements have been made by the Army Council for military cases.

The circular proper closes by intimating a similar coöperation to that existing between the Local Government Board and the Army Council, between the Board and the Lords Commissioners of the Admiralty.

Appended to it, with the consent of the Army Council and the Home Office, are extracts from official documents which may be of use to local authorities in the circumstances. This appendix contains:—

(1) Reprint of Local Government Board Circular, Oct. 21st, 1914 (general system of coöperation); (2) letter from Army Council to General Officers Commanding, Oct. 10th, 1914 (general system of coöperation); (3) letter from Army Council to General Officers Commanding, Oct. 31st, 1914 (payment of charges for sanitary services); (4) Local Government Board Memorandum to Army Council, Dec. 1st, 1914 (as to some results of inspection; circulated by the Army Council); (5) extracts from "Rules as to Billeting" (issued with Army Orders, Dec. 1st, 1914); (6) letter from Home Office to Chief Constables, March 6th, 1915 (as to importance of observing Rule 21 as to billeting); (7) letter from Army Council to General Officers Commanding, Oct. 18th, 1914 (payment for military cases in isolation hospitals); (8) letter from Army Council to General Officers Commanding, Dec. 23rd, 1914 (additions to isolation hospitals); (9) letter from Army Council to General Officers Commanding, Oct. 1st, 1914 (inspection of food); (10) letter from Army Council to General Officers Commanding, March 3rd, 1915 (as to means for reducing overcrowding in huts and billets).

The first of these reprints recapitulates a circular letter issued by the Local Government Board on August 31st,[1] which, in setting out the lines of action on which medical officers of health should coöperate with the military sanitary services, comprised the following points:—

(1) That each medical officer of health should place himself in communication with the local military authorities offering his services; (2) that each medical officer of health should give information and assistance to military sanitary officers as to water-supplies, disposal of refuse, drainage and conservancy arrangements, control of infectious disease, &c.; (3) that the assistance of the sanitary inspector should be secured; (4) a system of inter-notification of infectious diseases, both by military and civil sanitary officers, was arranged; (5) the value of antityphoid inoculation was indicated; (6) the probable need for increased hospital accommodation for small-pox and enteric fever was emphasised; (7) the services of the medical staff of the Board were offered to medical officers of health for consultation, and local visits by medical inspectors were announced.

The circular letter adds that the officers concerned acted promptly upon that letter, and after recapitulating the prescribed duties of the medical officers of health, proceeds to indicate that the duties of the district medical officer of health of a sanitary district in which troops are quartered should include:—

1. Inquiring for and bringing to the notice of the sanitary authority any conditions in which sanitary services can be rendered by them to the military population—e.g., by extending water mains, opening or extending sewers, providing latrines or baths, providing hospital accommodation for cases of infectious disease, disinfecting clothing and blankets, destruction of refuse, making special arrangements for scavenging. Reports on these matters should be dealt with as urgent, and special meetings of the local authority should be called to consider them if necessary. Copies of all such reports should be sent to the Board.

2. Inspecting systematically billets and also camps or other places solely in military occupation as to water-supply, methods of disposal or removal of all solid and liquid refuse, general cleanliness, and for the prevention of exposure to infection.

3. Taking action by recommendations to the military authorities, by reports to the sanitary authority, or otherwise, with a view to the removal of any dangerous or objectionable conditions.

4. Giving information to the medical officer with the troops as to local cases of infectious disease as soon as they come to knowledge, and as to any localities, premises, bathing places, &c., which on health grounds should not be frequented by soldiers. In some districts troops will need to be cautioned against the consumption of sewage-polluted shell-fish. Two copies of the Board's weekly report as to infectious disease will be sent to each medical officer of health. One of the copies should be handed to the medical officer locally in charge of troops, in addition to the immediate notifications indicated above.

5. Ascertaining in association with the county medical officer of health what hospital provision is available for cases

---

[1] THE LANCET, Oct. 31st, 1914, p. 1053.

> of infectious disease among troops in the district, and assisting in making arrangements for such provision. Existing civil resources should be made available to the greatest practicable extent for infectious cases among troops, care being taken not to diminish the accommodation for the civil population unduly.

The rest of this valuable reprint deals with the precautions to be taken by the sanitary executive in respect of the establishment of billets; the value which the services of the county medical officer will be to the military authorities by virtue of his consulting relations with district medical officers; and the machinery by which the recommendations of medical officers of health should be made to the military authorities.

The second reprint is a letter from the War Office enjoining upon general officers commanding in chief the necessity of coöperation in reference to the quartering and encampment of troops with the civil sanitary authority; and the third is an expansion of the same subject, whence the following may be quoted:—

> 1. As already pointed out in previous correspondence, it is necessary that there should be the closest coöperation between the civil and military sanitary officers in coordinating sanitary measures necessitated by the sudden influx of a large additional population.
>
> 2. In many cases it will not be possible to dissociate civil from military services, and, wherever it can be arranged, the sanitary services for the combined population should be carried out by the civil authorities. The adjustment of additional expenditure thus thrown on the local authorities will be carried out on the following lines.
>
> 3. The cost of additional scavenging in connexion with premises occupied by troops, whether hired premises or billets, may be refunded to local authorities, preferably at an arranged rate, based on the number of troops in occupation, rather than in the form of an account of expenses of actual collection, cost of appliances, disinfectants, &c.; cases of difficulty may be referred to the War Office for instructions.
>
> 4. The actual cost of special services specifically performed for the troops, such as the erection of latrines, extending water mains, &c., may also be refunded.
>
> 5. It is recognised that considerable additional expenditure of a recurrent nature may be incurred in connexion with various sanitary services, which, although not connected with the premises occupied by the troops, arise definitely out of military requirements—e.g., it may be necessary, in the interests of the health of the military as well as of the civil community, when large numbers are in billets: (*a*) to arrange more frequent clearances from all houses, whether occupied as billets or not; (*b*) to incur additional expenditure in connexion with professional services of medical officers, inspectors of nuisances, &c. Wherever practicable, such measures should be arranged beforehand between the military and civil authorities, and the additional cost may be refunded, provided general officers commanding are satisfied as to the reasonableness of the measures taken and of the amount claimed.
>
> 6. In the case of expenditure under 5 and 6, regard should be had to the fact of the continuous payments under paragraph 4. (Indeed, it may be possible in some cases to provide for such expenditure by inclusion in the arranged rate suggested in that paragraph.) In this connexion, however, Army funds should not be called upon to meet expenditure on special measures which are really necessitated by the inadequacy of *existing* sanitary conditions, and which may be aggravated, but not specifically created, by the increase in population; any case of dispute in this respect should be referred to the War Office.
>
> 7. For the present all claims on account of capital expenditure, other than those contemplated at paragraph 5, should be referred to the War Office with a full report of the circumstances and the recommendations of general officers commanding.
>
> 8. Arrangement should be made, as a rule, for local authorities to submit monthly claims of recurrent expenditure. Claims for capital expenditure should be rendered separately.

The letter closes by saying that only general lines are indicated, that economy must be preserved, and that everything said refers equally to detention camps.

The fourth reprint is a report from the Local Government Board with respect to inquiries in camps and localities occupied by troops up to Nov. 30th, the inquiries having been made by the inspectors of the Local Government Board. The examination of the various billets was obviously undertaken with considerable vigour.

The fifth reprint consists of extracts from the rules of billeting, which were issued with army orders last December.

The last five reprints are very brief, and the summary already given indicates their purport.

A valuable addendum to the circular letter consists of notes on the inspection of billets and camps by medical officers of health. On these we comment in a leading article upon the whole document.

ROYAL COLLEGE OF SURGEONS IN IRELAND AND THE WAR.

An emergency meeting of the Royal College of Surgeons in Ireland was held on March 31st to grant licences to students who had recently qualified. The licentiates having been admitted, the President, Mr. Conway Dwyer, referred to the services rendered by members of the College in the present war. One of the objects of the College, as set out in the original charter, was "to provide a sufficient number of properly educated surgeons as well for the service of the public in general as for that of our navy and army." At the present time over 600 Licentiates of the College held commissions in the Royal Army Medical Corps. No less than 28 of these had been mentioned in despatches in the present war; three had been made Companions of the Order of St. Michael and St. George; four had received the Distinguished Service Order; and one, Captain W. F. M. Loughnan, R.A.M.C., had been the first medical man to receive the Military Cross, "for gallantry on many occasions in Flanders in assisting to rescue the wounded whilst exposed to heavy fire." Captain Loughnan, who was present, being at home wounded, was heartily congratulated.

NOTES FROM THE GERMAN MEDICAL PAPERS.

The following notes have been sent to us by a correspondent in a neutral country who has been able to secure copies of German and Austrian medical journals:—

> A sign of the times is the shifting of interest in the treatment of tetanus and other anaerobic infected wounds to the prophylaxis and treatment of typhus, including in the term both T. abdominalis (our typhoid fever) and T. exanthematicus (gaol and famine fever.) The usual expectant treatment of typhoid fever has sufficed to give excellent results in the military hospital at Strassburg, under Professor von Tabora, the death-rate being scarcely above 5 per cent., and comparing favourably with peace statistics. Not a single case of infection of the staff had been observed, a result attributed to the daily inspection of the 200 helpers, when all had to show their hands; this was before prophylactic inoculation was practised. The diet was limited to 5–7 cups of milk daily (each of 180–200 c.c.), with 4–5 cups of fairly thick gruel. Bath treatment was found impracticable with the available helpers, and had been entirely replaced by pyramidon internally; 7 tablespoons of a 1 per cent. solution in 24 hours (= 1·05 grm. daily), gradually reduced but not omitted until the fifth to seventh day of defervescence. Heart failure was avoided by giving digitalis early in all cases, six times

0·1 grm. of digipuratum, the tolerance being extraordinary, and the mortality from intoxication or heart failure less than 1 per cent.

Professor Goldscheider, a physician with the army, reports on the vaccine treatment of typhoid, having been induced to try it by the experience of a prophylactic dose which happened to fall in the prodromal period. The Marx vaccine was used in a dose of 250–750 million bacilli. Fifty-seven cases were so treated, and in 55 out of 70 injections a remission of fever followed on the first to third day, lasting an average of two days, and sometimes coinciding with the final defervescence. In the remaining cases there was an increase of fever, but not of a serious character. Otherwise no special effect on symptoms was observed, the local reaction being less than in the healthy subject. Nor was any influence of a previous prophylactic inoculation to be observed. Unfortunately in the more severe cases of disease only the smaller doses of vaccine could be employed. Dr. M. Rhein records a smaller series of cases at Strassburg using the Halle vaccine diluted 1 in 20, a dose of 0·6 to 1·4 c.c. into the ulnar vein. In 94 per cent. of patients a rise of temperature with rigor followed in from half an hour to 2½ hours with subsequent rapid defervescence. Nine cases out of 33 were completely successful with one injection, another case with two—in all a high eosinophilia (100–200 cells per c.mm.) being noted along with an absolute leucopenia.

From Professor Ziegler's hospital at Freiburg i.Br. comes an encouraging account of an attempt at auto-serum-therapy. 50 c.c. of blood were withdrawn, phenolised, and 2·5 to 4 c.c. of the serum injected daily sub cutem on the outer side of the thigh. In 14 out of 18 cases improvement was rapid, the temperature falling in 2–5 days, often with marked sweating, coma especially clearing after three or four injections, the patients expressing great relief. The cases so treated were nearly all severe ones, but were all able to be up within four weeks; twice a sudden drop of 2·5° C. was noted with small but not frequent pulse, amenable to camphor. This, as well as the therapeutic effect in general, is to be probably ascribed to bacteriolysis, an explanation given by Hammerschlag as early as 1893. Professor Matthes, of Marburg, is working with a trypsin solution of typhoid bacilli filtered clear as an immunising agent, which has already given encouraging results with guinea-pigs. Writers all assume that the merits of the prophylactic inoculation are still on trial, and that it will still be long before exact figures are available. Of immediate effects the percentage of serious harm is very low. Under Professor Penzoldt at Erlangen, out of 4000 injections in 1780 persons only 6·8 per cent. had fever above 38° C. and 0·2 per cent. above 39° C. In two cases, aged 28 and 33 years, thrombosis occurred once in the forearm, and once an embolic thrombus of the leg. In a third case, a few hours after the second prophylactic injection, the temperature rose to 39·6° C., followed by typical splenic enlargement, roseolar rash, and bronchitis and exitus 14 days later from intestinal hæmorrhage. Menzer had already recorded a case with diarrhœa and roseola, and Professor Penzoldt inclines to the assumption of an aggressin action of the dead bacilli on a concurrent living infection. At Strassburg Professor Schlesinger, out of 1340 injections, never saw any serious local reaction; after the three injections 5 per cent., 3 per cent., and 2 per cent. respectively were unfit for service on the following morning, the indisposition differing from influenza in that improvement was almost always noted within 24 hours. Urticaria was not very uncommon, and in 5 to 8 per cent. the spleen was enlarged. Professor Weichardt (Erlangen) finds that local reaction is slighter with the newer vaccines sterilised at a lower temperature, there being no appreciable risk in their employment, as 0·5 per cent. phenol kills any living bacilli in the vaccine within 24 hours. Smaller doses at longer intervals will probably immunise as fully as larger ones at shorter interval.

The Temporary Employment of Members of School Medical Staffs in Military Hospitals.—The Board of Education has issued a circular to local education authorities alluding to the urgent need for more medical men in order fully to staff the additional hospitals required by the large forces now being placed in the field. In response to a question whether the Board would be prepared to facilitate the volunteering of officers of the School Medical Service for this hospital work the circular says that in cases where a school medical officer is also a medical officer of health, the Local Government Board must be consulted. So far, however, as the Board of Education is concerned, it assents freely. Should any school medical officer desire to volunteer the Board will raise no objection to his doing so even though his temporary absence may cause dislocation of the school medical service, assuming that local educational authorities will regard the matter in the same light and will give any medical officer, who desires to volunteer, leave of absence on such terms as will not involve any loss in his salary, status, or tenure. Arrangements can be made by which officers of the School Medical Service who join the Royal Army Medical Corps will be employed for home service only if they so desire, while they can offer themselves for service in military hospitals as civilians. In view of the pressing need for further medical assistance, facilities are being given to medical men who are serving as combatant officers in the Territorial Forces to transfer their services to the Royal Army Medical Corps of the Regular Army.

Vacancies for Medical Officers.—We are asked to state that medical men are urgently wanted for the R.A.M.C. (T.) 2nd London Division for the Sanitary Service, in the Field Ambulances, and also as regimental medical officers. Candidates for the Sanitary Service should possess the D.P.H. or have had some special training in preventive medicine. Those joining the Sanitary Service especially are likely to have an early opportunity of serving abroad. Applications should be made in writing, or preferably in person, to the Officer Commanding, Depôt Medical Units, 2nd London Division, Duke of York's Headquarters, Chelsea, S.W., who will be pleased to see intending applicants any day between 9.30 A.M. and 5 P.M.—Three medical men are urgently required to complete the establishment of the 2/1st Highland Mounted Brigade Field Ambulance, R.A.M.C. (T.). Full particulars as regards pay, duties, &c., will be given by Captain A. Mowat, officer commanding, 2/1st H.M.B.F.A., R.A.M.C., Houghton Hill House, Houghton, Huntingdon.

Relief Work in Serbia.—Sir Ralph Paget, who has been Assistant Under Secretary for Foreign Affairs since 1913, and has had an extensive experience in the diplomatic service since 1888, has been appointed British Commissioner for Red Cross relief work in Serbia, and will work under the joint committee of the Red Cross Society and the Order of St. John of Jerusalem. His wife, Lady Paget, who contracted typhus fever during her hospital work in Uskub, is happily now convalescent.—It has been announced that Dr. Ernest Magruder, of Washington, D.C., who, in company with other American medical men, went to render aid in Serbia, has succumbed to typhus fever there. Sister Augusta Minshull, of the Scottish Women's Hospital in Serbia, has also fallen a victim to the disease.

A meeting will be held in aid of the London Unit, Scottish Women's Hospitals for Serbia, on Monday, April 26th, at 8.30 P.M., at St. Marylebone Institute, 50, Paddington-street, W. Mr. Welby Fisher, of the Serbian Unit, British Red Cross, 1913, will give a lecture, illustrated by lantern slides, entitled "With the Serbians." Dr. Inglis will report on the work of the hospitals, prior to leaving for the front. Miss Cristitch, who has just returned from Serbia, will take the chair. Tickets of admission may be had on application to Mrs. F. W. Mott, 25, Nottingham-place, W.

Non-Alcoholic Buffets for Workers.—In a letter to the *Times* Mr. Howard Marsh suggests (in view of the proposed self-denying ordinance, with or without prohibition) the establishment of non-alcoholic buffets for workers, such as have already justified themselves in numerous centres where soldiers are quartered. The services of the Y.M.C.A. have been of the highest value in this direction. "In one of their institutions," he says, "or in some other sufficiently large room (in other cases tents have been used), a buffet has been provided, staffed, most willingly, by volunteers attending in relays, in many instances from 6 A.M. to 10 P.M. Three or four business workers have ordered in, and taken charge of, the supplies, and someone, used to accounts, has collected the daily takings, paid them into the bank, kept the books, and prepared them for audit. A tariff sheet has been so placed that it could be easily inspected. Sausage rolls, beef pies, ham sandwiches (of a size amply sufficient for "a snack at the bar") cost 2*d.*, a large cup of coffee and hot milk 1½*d.*, all other items—cake, plain bread and butter, and many others—1*d.* or less. A buffet worked on these lines, and when numbers are considerable, is quite a paying concern. As the items afford a good choice, are of good quality, and of moderate price, and well served, the buffet obviously meets a want and has been everywhere very popular. What has been done in a large number of cases for soldiers would be equally sound and beneficial in the case of men who are turning out war material and doing other heavy work." Mr. Howard Marsh further suggests the physiological importance of working the men in shifts.

THE EMPLOYMENT OF TRAINED NURSES IN MILITARY HOSPITALS.—The War Office has notified that nurses who have certificates of three years' training and are desirous of employment in military hospitals should apply, without delay, to the "Matron-in-Chief, Q.A.I.M.N.S.," War Office, for information as to conditions of service.

RUMOUR *v.* REALITY.—A lecture recently delivered at Lochinver, N.B., by Mr. W. S. Mackenzie calls forcible attention to the need for common sense and restraint in giving credence to the wild rumours that inevitably become current during periods of excitement. Stories had been put in circulation that the deaths at the military camp at Bedford had reached the enormous total of 300 and more during the month of January, largely due to an epidemic of measles. Mr. Mackenzie investigated the matter, and was able to state, from an official list in his possession, giving name, age, regiment, and cause of death, that from the first week of August up to March 6th there had been 78 deaths in all, of which measles, with all its complications, was responsible for 58. Mr. Mackenzie took a practical method of allaying the fears of his highland audience by offering to hand over the list to any responsible man selected by his auditors, and promising to pay £5 for the name of every member of the Highland Division who had died and whose name did not appear on the list.

GLASGOW MEDICAL GRADUATES AND THE WAR.—At the conferring of degrees at Glasgow University on April 1st Principal Sir Donald MacAlister said that he had already received the names of 384 graduates in medicine of the University who were on service with the forces of the Crown, and the list was by no means complete.

INSTRUCTION IN NURSING FOR BELGIAN LADIES.—It is announced that the Joint Anglo-Belgian Committee of the King Albert's Hospitals for Convalescent Belgian Soldiers have determined on the establishment in London, under the supervision of Professor Jacobs, of a training school where Belgian ladies may receive a course of training for nursing.

A DISTINGUISHED RECRUIT TO THE ROYAL ARMY MEDICAL CORPS.—The Earl of Crawford, who has done vigorous service in recruiting since the outbreak of the war, has now capped his patriotic service by himself enlisting as a private in the Royal Army Medical Corps. Lord Crawford, who was formerly a captain in the first volunteer battalion of the Manchester Regiment, as Lord Balcarres represented Chorley in the House of Commons from 1895 to 1913, and was Whip to the Conservative party. He studied social problems as a resident of the Oxford Settlement in the East End of London when the present Bishop of London was head of the institution.

MILITARY HOSPITAL AT ASCOT CLOSED.—As several cases of scarlet fever have broken out at the Military Hospital at Ascot the medical authorities at Aldershot have decided to close the hospital temporarily.

BLENHEIM PALACE AS A HOSPITAL.—The library of Blenheim Palace is being used, by the generosity of the Duke of Marlborough, as a hospital for wounded soldiers.

AT the annual meeting of the North Staffordshire Field Club, held in the new Central School of Science and Technology, Stoke, on March 23rd, Mr. W. Dunnett Spanton, F.R.C.S. Eng. and Edin., was elected president. The meeting marked the jubilee of the club, of which Mr. Spanton is an original member.

Medical News.

EXAMINING BOARD IN ENGLAND BY THE ROYAL COLLEGES OF PHYSICIANS OF LONDON AND SURGEONS OF ENGLAND.—At the quarterly examination in Practical Pharmacy held on April 9th, the following candidates were approved :—

Herbert Claude Apperly and Ralph William Codrington Ball, Middlesex Hospital; Mahmud Bayumi, Cairo and London Hospital; John Prichard Bracken, University College Hospital; Douglas Crellin, Cambridge University and St. Bartholomew's Hospital; Patrick Arthur Dargan, St. George's Hospital; Frederick Oloff Fehrsen, London Hospital; John Eskdale Fishburn, Portsmouth Municipal College; Arthur Alan Forty, Leeds University and Guy's Hospital; Leslie Stewart Goss, Oxford University and Middlesex Hospital; Bernard Heynes Greensill, Birmingham University; Rupert Bannatyne Hick, St. Mary's Hospital; George Gerald Jack and Vincent Coram James, Middlesex Hospital; David Joseph Heritage Jones, St. Mary's Hospital; James Phillips Jones, Guy's Hospital; Vladimir Kameneff, Moscow and University College Hospital; Nicholas Edward Kendall, Guy's Hospital; Maynard Lambert Loveless, Cambridge University and Middlesex Hospital; William Bird Loveless, Cambridge University and Middlesex Hospital; William George McKenzie, Bristol University; Thomas Walter Melhuish, Cambridge University and Middlesex Hospital; Sadek Girgis Moftah, Cairo and London Hospital; Edgar William Mottau, Ceylon Medical College and University College Hospital; Nava Ratnam Nalliah, Ceylon Medical College and London Hospital; Hallock Ratnarajah, Ceylon Medical College and St. Mary's Hospital; Arthur Lowry Robinson, University College Hospital; Malcolm Catchick Sarkies, Middlesex Hospital; Adolphe Gladstone Millott Severn, Guy's Hospital; Sydney Frank Simpson, King's College Hospital; John Greet Stevens, Guy's Hospital; Arthur Sunderland, Charing Cross Hospital; Godfrey Trehane Symons, King's College Hospital; Thomas Joseph Taunton, St. Bartholomew's Hospital; Robert Ockleston Townend, London Hospital; Arthur Reginald Stuart Warden, Cambridge University and St. Thomas's Hospital; Edward Scott White, Bristol University; and Israel Hyman Zortman, London Hospital.

FIRST EXAMINATION.

Janet Adeline Agnes Sang, William Bethune Stott, Rebecca Goodman, Muriel Keyes, Nathaniel Brownlee Watson, and Andrew Francis Briglmen.

Physics.—Max Gottschalk, John Kohler Steel, and Trevor Francis Thomas.

Biology.—Jung Bahadur Singh and Thomas Ferguson Minford.

Chemistry.—Gordon Spivey Woodhead, Alexander Forsyth Cuddell, John Lawson Gibson, Richmond Francis Kerr, and Thomas Ferguson Minford.

SECOND EXAMINATION.

Andrew Inglis Meek (with distinction), John Bruce Watson Telford, Mohammed Talaat, Patrick Joseph Murnane, Janie Isabel McBirnie, Agnes Emilie Keen, and Alan Herbert Brooke Hudson.

Anatomy.—Leslie MacDuff, Eduard Louis Adendorff, and Ernest Ebenezer Bronstorph.

Physiology.—Daniel Cornelius Howard, Hassan Amin Madwar, and Richard Gordon Bell.

THIRD EXAMINATION.

Zachariah Albert Green (with distinction), John Alexander Murray, John Alexander Tolmie, John Forbes Campbell, Frederick Charles Joseph Mitchell, Iwan Davies, Ernest Andrew Hamilton, Martha Hunter Hoshing, Phœbe Tripp, Frank Jones, and Paul Vertannes.

Pathology.—Indranarayan Borrah, William McElroy, and Stanley Wall Hoyland.

FINAL EXAMINATION.

Arthur Craig, William Leckie Coullis, Victor James Wilson, Bak Hin Ong, and Alamu Ojo Olaribigbe.

Surgery.—Charles Evelyn Meryon, John Murray Hiddleston, and Joseph Sydney Dickson.

Midwifery.—Nathaniel Benjamin Morris, Charles Evelyn Meryon, and John Murray Hiddleston.

Medical Jurisprudence.—Matthew McLintock Bainbridge, John Park Mathie, William Ainsley, Alexander Cray McKee, Douglas Charles Murray Page, Alexander William McGregor, William Alfred Backenstoe, Paul Lucien Manuel, Robert Christian Wilson Spence, William James Forsyth Craig, and Edward Spence.

UNIVERSITY OF GLASGOW.—The degrees of M.B. and Ch.B. were conferred on April 1st on the following :—

With commendation: Ronald Thomson Grant and Seymour Cochrane Shanks. Ordinary degrees: Ismail Abdurahman, George Kirkwood Allan, James Mair Anderson, William Ernest Boyd, M.A., Samuel Bryson, John Buchanan, John Munro Campbell, Alfred Mackenzie Clark, George Gibson Cooper, Henry Paterson Crow, Alexander Hogg Donaldson, Harry Taylor Findlay, George Fleming, George John Fraser, Ian Maclean Frazer, David Gould Gardiner, William Gordon, Thomas Cameron Houston, William Hunter Howat, Robert Kyle, Hugh Brown Lawrie, Alfred Thomas Logan, Donald Kerr MacDougall, Donald M'Donald M'Intyre, James Murdoch Mackay, Joseph Allan MacLean, Thomas Duff Miller, Janey Lamond Munro, Prem Nath, L.D.S., Thomas Augustine O'Brien, John Roberts Pate, James Paterson, William Burns Primrose, Alexander Forbes Ross, William Jack Scade, William Ballantine Stewart, Robert Sutherland Strachan, Robert Taylor, Cecil Raymond Tytler Thompson, Margaret Walker, William James Cunningham Watt, James Gordon Wilson, and Thomas Young.

University of Durham, Faculty of Medicine.—At the Convocation on March 27th the following degrees were conferred :—

Doctor of Medicine.—Reginald Cyril Herbert Francis.
Doctor of Medicine for Practitioners of 15 Years' Standing.—Matthew Leslie Guy Hallwright and Arthur King, M.R.C.S.
Master of Surgery.—John Hamilton Barclay.
Bachelor of Medicine.—Patrick Alexander Clements, Geoffrey Bede Egerton, Mary Sarah Gordon, William Herbertson, Charles Henry Keay, Herbert Arnold Lake, George Edward Stephenson, William Stott, and Edgar James Tyrrell.
Bachelor of Surgery—Patrick Alexander Clements, Geoffrey Bede Egerton, Mary Sarah Gordon, William Herbertson, Charles Henry Keay, George Edward Stephenson, William Stott, and Edgar James Tyrrell.
Diploma in Public Health.—Margaret Mair Miller.
Licence in Dental Surgery.—George Galloway Robertson.

In examinations for the Licence in Dental Surgery the following candidates have passed :—

Second Examination, Dental Mechanics and Dental Metallurgy.—Gainsford Reed and Wilfred Phillipson Spence.
Third Examination, Anatomy, Physiology and Histology ; Dental Anatomy and Dental Histology and Dental Materia Medica.—Douglas Edward Sayce and Lawrence Somerville-Woodiwis.
Final Examination, Surgery, Dental Surgery, Dental Pathology and Bacteriology and Operative Dental Surgery.—George Galloway Robertson.

London School of Tropical Medicine.—The following were the successful candidates at the examination held at the end of the forty-seventh session (January–April, 1915) :—

G. Campbell* (with distinction), W. L. Peacock (Colonial Service), R. Bruce-Low (Colonial Service), E. Banos, W. J. J. Arnold (Colonial Service), and P. T. Patel.

* This candidate has been awarded the Duncan medal of the London School of Tropical Medicine, this being given to the student who obtains the highest aggregate of marks during the session.

University of Liverpool.—The Diploma in Tropical Medicine has been obtained by the following gentlemen: J. F. Lobo, L.M.S., G. D. Madhok, L.R.C.P. & S., L.F.P.S., and K. V. Swami, L.R.C.P. & S., L.F.P.S.

Donations and Bequests.—By will the late Miss E. M. Green, of Brighton, left £1000 to the Brompton Hospital for Consumption, and £500 each to the Brighton, Hove, and Preston Dispensary, and the Brighton, Hove, and Sussex Throat and Ear Hospital. The residue of her property the testatrix left equally between the Cancer Hospital, Fulham ; the Royal Hospital for Incurables, Putney ; and the British Home for Incurables, Streatham.—Mr. Thomas Critchley, of Blackburn, has given £1000 to the East Lancashire Royal Infirmary to endow a bed to be named after himself and his wife.—Under the will of the late Mr. Joseph Kitchingman, of Nook, Liscard, the testator left £2000 for the maintenance of two beds in the Victoria Central Hospital, Liscard ; and £1000 to the Warrington Infirmary.

Centenarians.—The death is announced of Mrs. Elizabeth Deacon, of Croydon, in her 103rd year. She retained all her faculties, and only quite recently wore spectacles.—Mr. Henry Preston, of York, has just celebrated his 100th birthday.

The annual meeting of the Medical Missions Department of the Society for the Propagation of the Gospel in Foreign Parts is to be held in the Great Hall of the Church House at 8 P.M. on Wednesday, April 21st. The chair will be taken by Sir Francis H. Champneys, Bart., M.D., and the speakers will be Mrs. Ferguson-Davie, M.D. of Singapore, and Dr. H. H. Weir, of Corea.

Mr. F. M. Fisk, who has been manager of the London Branch of the firm of Parke, Davis and Co. since it was established in 1891, died on Saturday last. Mr. Harry Fisk, who has for some years occupied the post of assistant manager, has been appointed manager of the branch.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

THE TRAINING OF INDIAN MIDWIVES.

A SCHEME devised by Lady Willingdon has been recently put forward at Bombay. It is proposed to create an interest in the work done by the Bombay Sanitary Association towards reducing the infant mortality and the dangers to mothers, due to the ignorance and superstition of the native midwife and the women who employ her. It is quite apart from training nurses for India or training Indian women as nurses. In India there is a class which cannot be reached by providing trained nurses unless they are taught to appreciate them and can afford to employ them. The aim is to put the native *dai*, or midwife, under trained supervision. It will be impossible to supersede these women at once, but a good deal can be done, by bringing them under control and by legislating on the lines of the Midwives Act, England, 1902, gradually to replace them. The position of these native *dais* must, however, be taken into consideration. In some cases they are hereditary holders of the title. They cannot take the place of the trained nurse, but they might with advantage be got into touch with health visitors until the demand is created for a better trained class of nurse, resulting in a reduction in the infant mortality and risk to the mother. In Bombay there are ten municipal district nurses and five health visitors, who attend poor women in confinement and give instruction in personal and domestic hygiene; they are empowered to give aid in the shape of a bed, blanket, milk, &c., and disinfectants to women who are certified by a magistrate to be in a deserving condition. There are ten municipal dispensaries, and at each of them these native women have been collected and a course of demonstrations and instructions given to them in their own language. It is now sought to provide ten more trained women, and shortly to have a maternity home where poor women may go for confinement and where native *dais* will be trained. The idea is to get to know these women and their methods and induce them to call in skilled aid and ask for the help of a municipal trained nurse free of charge, and to notify all births and deaths to the Health Department, and all cases of sickness among women.

It must be understood that this movement is an educative one directed, first, at removing some of the risks by controlling the *dais*; and secondly, by providing more lady health visitors to induce mothers to ask for more skilled attendance by visiting the homes and explaining the advantages.

INSTRUCTION IN PRACTICAL BEE-KEEPING.

To the Editor of THE LANCET.

SIR,—I have received a letter from the British Bee-Keepers' Association informing me that courses of instruction and demonstrations in practical bee-keeping will be given throughout the spring and summer months at the Educational and Experimental Apiary of the British Bee-keepers' Association in the Zoological Gardens, Regent's Park, and that full particulars can be obtained from Mr. W. Herrod-Hempsall, the secretary, 23, Bedford-street, Strand, W.C. The association makes no profit whatever on these lectures and demonstrations; in fact, it was only by the financial assistance received from the Development Commissioners that the apiary was established in the Zoological Gardens. I would remind your readers that the bee-keeping industry enables an additional and very substantial profit to be obtained from the land, and that the production of fruit almost entirely depends upon the visits of honey bees for the fertilisation of fruit blossoms.

I am, Sir, yours faithfully,
April 12th, 1915. J. BERNARD LAMB.

THE ARMCHAIR EXPERT.

IN the current issue of the *Craigleith Hospital Chronicle*, "our own military expert, a gentleman as intimately in touch with the Headquarters' Staff as any other expert who fills an armchair," contributes some Notes on the Military Situation which an imaginary Censor believes to be "as instructive as any similar notes I have ever had the pleasure of censoring. Please send me some more of the same." The notes, from which we extract the following, are excellent nonsense:—

A correspondent asks me the pertinent question: "Since the Kaiser has given 85 whole holidays and held 69 commemoration services to celebrate the total annihilation of his enemies, how is it that the war still continues?" The point raised is interesting, and the answer undoubtedly must be that the holidays were given first and the annihilations arranged afterwards. The weather then presumably intervened, and so the latter part of the programme had to be postponed. [*Note by Censor*—"Passed, but how did you learn all this?"] Another correspondent inquires why copper is so important for our enemies, since he always understood that iron was the metal employed in the manufacture of armaments. The answer to this unquestionably is that the iron is at present required to make crosses, and as the value of each of these is about a copper that metal is naturally in considerable demand. [*Note of Censor*—"Passed, but please stop now."]

The notes bear the signature of Mr. J. Storer Clouston, who has to his credit, in "The Lunatic at Large," one of the drollest works of recent times.

LEAVING THE COFFIN IN THE PORCH.

To the Editor of THE LANCET.

SIR,—Will you allow me to suggest a "funeral reform"? Invariably, under all circumstances, the coffin should be placed in the porch and never taken *inside* the church, whether the deceased has died from infectious illness or not. The coffin should be in the care of the undertaker in the porch until the mourners come out of church after the first part of the funeral service. One can hardly imagine how such a senseless custom as the present one could have ever come into vogue. But whatever be its origin, it is most unwise from a sanitary point of view under any circumstances or at any time of the year. The precaution is especially necessary now that spotted fever has appeared in several places.

I am, Sir, yours faithfully,
April 10th, 1915. ÆSCULAPIUS.

MISSED ABORTION.

A MEDICAL correspondent, signing himself "Carnis," sends us the following upon which he invites comments: An exceptionally strong and healthy married woman, 26 years old, with one child 4 years of age, had her last regular menstruation at the end of January. At the end of the following May a red and brown discharge set in per vaginam, occurring on alternate days and lasting for six weeks, when it ceased, amenorrhœa following. At the end of March in the succeeding year she felt abdominal pains, accompanied by a watery discharge per vaginam, which lasted for three days, when a carneous mole, measuring 4 inches in length and 3½ inches in circumference, was expelled. On cutting open the mole no trace of a fœtus or cord could be seen, but a number of nodules of various sizes projected from the anterior wall of the cavity. The lining and surface of the mole were smooth. Very little hæmorrhage accompanied the expulsion.

A GOOD DINNER FOR THREEPENCE.

THE Central Committee on Women's Employment is doing sensible work in demonstrating through its training kitchens that the price of good living is a matter of sound domestic economy and competent culinary art. Where many people are to be fed, the cost of a good dinner is being reduced as low as 3*d.* a head. This dinner consists of either boiled fish, with parsley sauce, potatoes, and baked syrup rolypoly pudding; or roast mutton, greens and potatoes, with stewed apples and custard. Upwards of 1500 dinners are being supplied weekly from six centres to the women who work in the Queen's Work for Women Fund Workrooms. In many households nearly as much food is wasted as is eaten. But, apart from wilful waste, the waste arising from uneconomic methods and abominable cookery is as detrimental if less criminal.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

The following magazines, journals, &c., have been received:— Maryland Medical Journal, Modern Hospital, Surgery, Gynecology, and Obstetrics, Journal of Anatomy and Physiology, Science Progress, Journal of Comparative Pathology and Therapeutics, Annales de l'Institut Pasteur, American Journal of Medical Sciences, Archives of the Roentgen Ray, &c.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Lord Rayleigh, O.M.: Deep Water Waves, Progressive or Stationary, to the Third Order of Approximation.—Hon. R. J. Strutt: A Chemically Active Modification of Nitrogen, produced by the Electric Discharge. VI.—Dr. C. Chree: The Difference between the Magnetic Diurnal Variations on Ordinary and Quiet Days at Kew Observatory.—Mr. F. Horton: The Effects of Different Gases on the Electron Emission from Glowing Solids (communicated by Sir J. J. Thomson).—Mr. W. S. Tucker: Heats of Dilution of Concentrated Solutions (communicated by Prof. H. L. Callendar).—Mr. T. R. Merton: On the Origin of the "4686" Series (communicated by Prof. A. Fowler).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY.

SECTION OF THERAPEUTICS AND PHARMACOLOGY (Hon. Secretaries—W. Langdon Brown, Philip Hamill, J. Gordon Sharp): at 4.30 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1915-1916.

Discussion :

On the Treatment of Phthisis by the Induction of Pneumothorax, to be opened by Dr. T. D. Lister, who will give a demonstration of the apparatus.

Dr. Jane Walker, Dr. S. Vere Pearson, Dr. Lillingston, Dr. de Carle Woodcock will take part in the discussion.

GENERAL MEETING OF FELLOWS: at 5 P.M.

Ballot for the Election of Candidates to the Fellowship.

FRIDAY.

SECTION OF EPIDEMIOLOGY AND STATE MEDICINE (Hon. Secretaries—G. S. Buchanan, William Butler): at 8.30 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1915-1916.

Dr. H. E. Corbin: Small-pox among Cotton Operatives.

Dr. E. L. Collis: The Occurrence of an Unusual Cough among Weavers of Cotton Cloth.

(Members desiring advance proofs should communicate with Dr. G. S. Buchanan, Local Government Board, Whitehall, S.W.)

RÖNTGEN SOCIETY, Institution of Electrical Engineers, Victoria Embankment, W.C.

TUESDAY.—8.15 P.M., General Meeting. Papers:—Dr. N. S. Finzi: Late Radium and X Ray Burns.—Mr. F. H. Glew: A New Alpha Ray Effect.—Mr. A. O. Forder will exhibit a New Plate Holder.

MEDICO-LEGAL SOCIETY, 11, Chandos-street, Cavendish-square, W.

TUESDAY.—8.30 P.M., Exhibition of Specimens. Mr. J. H. C. Sproule: Medico-Legal Experiences in Ceylon.—Dr. R. Burrows: The British Medical Association Report on Crime and Punishment.

SOCIETY FOR THE PROPAGATION OF THE GOSPEL IN FOREIGN PARTS (MEDICAL MISSIONS DEPARTMENT), Great Hall of the Church House.

WEDNESDAY.—8 P.M., Annual Meeting. Speakers:—Mrs. Ferguson-Davie, M.D. (Singapore) and Dr. H. H. Weir (Corea).

HARVEIAN SOCIETY OF LONDON, Stafford Rooms, Titchborne-street, Edgware-road, W.

THURSDAY.—8.30 P.M., Discussion on Epidemic Cerebro-spinal Meningitis (opened by Dr. F. E. Batten). Followed by Dr. D. N. Nabarro, Dr. J. A. Arkwright, and Dr. L. Colebrook.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Museum Demonstrations for Advanced Students and Medical Practitioners:—

MONDAY.—Mr. Shattock: Specimens of Spina Bifida.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Mr. B. Fletcher: The War on Rheims. (Lecture II.)

THURSDAY.—3 P.M., Prof. A. S. Eddington: The System of the Stars: The Stellar System in Motion. (Lecture II.)

FRIDAY.—9 P.M., Major P. S. Lelean, R.A.M.C.: Military Hygiene at the War.

SATURDAY.—3 P.M., Lieutenant-Colonel A. G. Hadcock: Modern Artillery. (Lecture II.)

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year ... — ...	£1 1 0	One Year — — ...	£1 5 0
Six Months ... — ...	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Communications, Letters, &c., have been received from—

An Address

ON

WOUND INFECTIONS

AND ON

SOME NEW METHODS FOR THE STUDY OF THE VARIOUS FACTORS WHICH COME INTO CONSIDERATION IN THEIR TREATMENT.

Delivered before the Royal Society of Medicine on March 30th,

By COLONEL SIR A. E. WRIGHT, M.D., F.R.S.,

A CONSULTING PHYSICIAN TO THE EXPEDITIONARY FORCE.

(*From the Research Laboratory attached to No. 13 General Hospital, Boulogne-sur-Mer.*)

(*Continued from p. 792.*)

We may, with such new knowledge as we have won from the experimental methods I have described, now revert to the consideration of those three methods of combating wound infections which were enumerated earlier in this discourse. It will be remembered that these were: *treatment by antiseptics; treatment by physiological methods;* and *vaccine-therapy*. We will take them one by one.

TREATMENT BY ANTISEPTICS.

If we were to adopt the Socratic method, and were to inquire of the first man whom we might find engaged in washing out a wound what were the grounds for his confidence in the utility of his procedure, he would probably make some such answer as the following: "I know that the antiseptics which I am bringing into application are agents which directly kill and inhibit the growth of microbes. There is no other agency known which would be competent to do the bactericidal work that these antiseptics do in the wound. And, again, it is everybody's knowledge that Lister, by bringing in his antiseptic treatment, extirpated those septic infections of wounds, which before the advent of his method devastated the surgical wards of every hospital."

And if we were to push our question further, and to ask of the surgeon what was the particular end and object to which his procedures were directed—whether it was the sterilisation of the wound; or the killing off of a large proportion of the microbes; or the imposition of a check upon the survivors; and if we were further to ask, whether the particular antiseptic in the particular strength in which he was employing it could be relied upon to achieve the end in view; we should probably be told that, supposing that the antiseptic did not completely sterilise the wound, it would inevitably kill a large number of microbes; and it would probably also inhibit the growth of any survivors. And, inasmuch as one or other of these objects would be sure to be achieved, there could be no question but that advantage would be accruing to the patient.

We should, in short, get an answer which proceeded upon at least one erroneous premiss, and which betrayed loose and inconsequent thinking, and a reluctance to come to close quarters with the question. But the reasonings of the larger part of humanity are neither better nor worse than this, and it is not for that less necessary to take them into very serious account, and to do our best to correct them when they mislead.

Let us begin, since Lister is the fount and origin of all antiseptic treatment, with what relates to his work. Lister's name is associated with two discoveries. The *first* of these is the discovery that we can, by an *anticipative prophylactic application*, hold off microbes from surgical wounds, and so avoid wound infections. The *second* is that in cases of compound fracture where the wound is already infected we can still, by what I may perhaps call a *retrospective prophylactic application of antiseptics*, stave off the wound infection. The first of these is a discovery of absolutely universal application, and it will carry the name of Lister down to remotest posterity. The second discovery has reference only to a particular kind of traumatic wound, and shows that prophylactic applications of antiseptics can be usefully employed also in connexion with some wounds which are already infected.

It is clear that neither of these discoveries finds any direct application either in connexion with prophylaxis or the treatment of the wound infections which occur in projectile wounds.

What it is necessary to say on the possibility of preventing septic infection by sterilising projectile wounds can be said in a very few words. The principle that microbes can be held off from wounds by an antecedent employment of antiseptics has no application to projectile wounds, for these are infected before they are seen by the surgeon. Nor, again, is the Listerian discovery that prophylactic applications of antiseptics can in the ordinary compound fractures of civil life stave off wound infection, a discovery which relates to conditions such as obtain in projectile wounds. Retrospective, or as we may also call them *ex post facto*, prophylactic applications of antiseptics will give good results only when the microbes are accessible. In the case of the ordinary compound fracture of civil life this is the case. For here the microbes lie exposed on the external surface of the bone which has been thrust through the skin. The contrary holds for projectile wounds. Here the microbes are inaccessible. They have been carried down deep into the tissues, and lie on the inner face of a torn and ragged track, and that track is blocked by blood clot and hernia of muscle.

It is clear that the utmost that prophylactic applications of an antiseptic could under such conditions achieve would be an incomplete sterilisation. And an incomplete sterilisation would leave us with a wound infection, and in a few days with as bad an infection as before. Coming now to actually subsisting wound infections, we see that exactly the same thing would apply. We are not entitled to infer from the fact that the method of Lister is within its limitations an effective method of prophylaxis, that it is also an effective method of treatment. That is clearly a question which must be determined as an independent issue.

When we approach the question in this way we see that the first point which has to be determined is: What particular concentration of each particular antiseptic will, when applied to the wound, exert there a bactericidal action on the microbes? In connexion with this we must beware of the fallacy of taking the figures for an antiseptic acting on microbes in watery suspension and seeing in these an all-round formula of efficacy for that particular antiseptic.

A formula of efficacy of this sort might, of course, find a useful application where the sterilisation of skin surfaces and instruments was concerned. For here the antiseptic comes into operation on exposed microbes in full strength. In practically every other case the conditions would be entirely different. The antiseptic would have to come into operation in a medium which quenches its antibacterial action.

I have recently, in dealing with internal medication by antiseptics in pneumonia, brought forward[1] an array of experiments which show that the quenching of the antibacterial power of antiseptics by the medium in which these come into application, is the essentially important factor to be considered in connexion with their therapeutic use. In particular I have shown in connexion with drugs like creosote and guaiacol that doses which would almost certainly be lethal would have to be administered before these could come into operation in blood.

The same sort of thing holds true of pus. But here the situation will be different in two respects. It will be different in respect that, as compared with serum, pus exerts a greater quenching effect upon antiseptics. It is, if I may put it so, more *antisepticotropic*. This will prevent us taking the antisepticotropic values for the serum and applying them to the pus in the wound. Again, the conditions under which an antiseptic will come into application in a wound will contrast with those which come into application in internal medication. In connexion with internal medication we have to take into consideration the quenching influence which would be exerted by the totality of blood. In applying antiseptics to the wound it lies with us to make the conditions much more favourable to the antiseptic. We can, if it is a question of washing out a wound with antiseptics, make the relation of antiseptics to pus anything that we please. And where it is a question of leaving an antiseptic behind in the wound for the purpose of inhibiting growth, we can also, within limits, lay down our own conditions, and make provisions which will prevent the conditions becoming too unfavourable to the antiseptic.

If there are, in the published literature on antiseptics, any papers dealing with the investigation of the efficacy of antiseptics from this point of view, they have escaped my observation; I have, accordingly, in conjunction with my fellow-workers, Dr. W. Parry-Morgan and Dr. A. Fleming, set to work to supply the missing data. To find out what concentrations of antiseptic ought to be brought into operation in washing out a wound, we took 9 volumes of antiseptic to 1 of pus. To determine what inhibitory effect would be exerted by an antiseptic left behind in a wound, we took one portion of the antiseptic to—as the case might be—2 or 4 volumes of pus. It will be seen that by this plan of operation we conduct our experiments directly on the microbes and pus furnished by the wound: in other words, instead of dealing with any abstract question, we deal with the concrete question which presents itself in the particular wound infection which happens to lie before us.

The general results obtained in this investigation will be separately set forth. At the moment it will suffice to call attention to the fact that when employing 9 volumes of the antiseptic solution to 1 of pus from the infected wound, and leaving the antiseptic in application for ten minutes, a strength of 1 in 40 of carbolic acid, and strengths of 1 in 400 of biniodide of mercury, and 1 in 500 of tincture of iodine all failed to sterilise. Again, in experiments on inhibition, 1 volume of a 1 in 30 dilution of lysol, and 1 in 400 of tincture of iodine, and 1 in 200 solution of biniodide of mercury did not avail to prevent bacterial growth in 4 volumes of pus. But I must not delay over the question as to what will, with a particular antiseptic, be the particular concentration required for the attainment of a particular antibacterial effect. Let us revert to our task of trying to bring the whole question of the employment of antiseptics in wounds into some sort of proper perspective. It will help us to do this if we consider the following questions:—

(1) *Is there any reasonable prospect of sterilising the wound by an application of antiseptics?*

So far as the pus which is brought into intimate contact with the antiseptic is concerned, it would probably be possible to sterilise this by methods which will elsewhere be explained. But we have in the wound not only pus which can be reached by our antiseptic washings, but also pus which is locked up out of reach in blind alleys and pockets. And, again, we have in the infected wound not only a microbic infection of discharges, but also a microbic infection of the granulation tissue. And assuredly the really formidable difficulty in connexion with the sterilisation of the wound is that of getting sufficient penetrating power to deal with these sheltered microbes.

Now the ordinary antiseptics which we employ in wounds have as good as no penetrative power, and though it is possible to undertake comparative experiments, and, as an interesting academic exercise, to determine for a series of antiseptics how far their antibacterial influence may extend in agar or any other artificial medium, academic exercises like this ought not to divert our attention from the fact that there is not, among all the competing antiseptics, one which can penetrate into and sterilise the walls of an infected wound. In fact, if it were ever to come about that an antiseptic sterilised heavily infected wounds, that would be a matter to announce in all the evening and morning newspapers. Nor is it matter for surprise that antiseptics should not be able to penetrate into granulation tissue. Let us call to mind the fact that this is composed of continuous layers of cells; that the cell wall is a quasi-impenetrable membrane; further, that we have in the granulation tissue a very developed system of capillaries, capable of absorbing and carrying away any antiseptic that might penetrate; and, lastly, that we have also in the granulation tissue an outflowing lymph current. Having realised the inefficacy of antiseptics for the purpose of sterilising an infected wound, let us now pass to the next question. It may be formulated thus:—

(2) *Is there in point of fact any ground for the confident belief that a reduction in the number of microbes such as would be obtained by washing out of the wound with antiseptics must carry advantage to the patient?*

We have realised that it is a firmly established conviction that every procedure which leaves behind in the wound fewer microbes would, like a smaller sowing of seed, sensibly reduce the ultimate crop, and so sensibly advantage the patient. The bacteriologist does not see in this a matter of course. He thinks not only of the sowing, but of the soil. He reflects that when we are dealing with a microbe which reproduces itself rapidly on a particular medium—let us say the typhoid bacillus in peptone broth—the lightness or heaviness of the sowing would after the lapse of a comparatively short time hardly come into account again in the case of a microbe which multiplied itself very slowly in a particular medium the sowing would, unless the incubation period were indefinitely extended, make very little difference to the result. Finally, where a microbe grows very slowly on a particular medium, but very rapidly as soon as this undergoes transformation, the population of microbes found in the culture would clearly depend less on the number implanted than on the time taken to convert the nutrient substratum from a bad into a good cultivation medium. It is, in the light of what has gone before, quite easy to see the application of this to the wound. Whether few or many serophytic microbes are left behind in the wound, will make comparatively little difference to the number found in the uncorrupted lymph. For serophytes will, unless constantly kept down by phagocytosis, multiply rapidly. Again, in the same way, whether few or many sero-saprophytes are left behind, would not make much difference to the number found in the uncorrupted discharge. For sero-saprophytes grow very badly on this medium. But the factor which will readily exercise a determining influence on the result will be the rate at which the lymph becomes corrupted. And the practical conclusion emerges that what is really difficult in dealing with an infected wound is not to thin out the microbes; but afterwards to keep down their numbers. We are here carried along by our train of thought to the "dressing of the wound"; and in connexion with this we may put the following question to ourselves:—

---

[1] Drugs and Vaccines in Pneumonia. Constable, 1914.

(3) *What conclusions can be drawn from the fact that frequent redressings are in connexion with the treatment of infected wounds by antiseptics indispensable?*

This is one of those questions of which we realise the fundamental significance, as soon as they formulate themselves in the mind. When our treatment has miscarried, and the wound has filled up again with pus, and this has become tryptic and has begun to digest the granulations and skin surfaces with which it comes into contact, and when bacterial poisons are being absorbed into the system, we are compelled to redress the wound. In other words, when we have been falling away we have to try to get back to the position which was reached at the previous dressing. And let us in this connexion note that it is one thing to be able when unsuccessful to fall back upon dressing, and to make of this a point of departure for trying a new way; and quite another thing to accept dressing as a necessary and inevitable element in our programme of treatment, and then not even to propose to make it a point of departure for a new therapeutic effort, but calmly to contemplate an everlastingly repeated setting out into a blind alley, and an everlastingly repeated return to our point from which we started. If grace had been given to us to see things with unsophisticated vision, it would be clear to us that to make constant redressing an integral and indispensable element in our programme of treatment is really as much of a confession of failure in the case of an infected wound as in a surgical operation. It is equivalent to saying that our method of treatment leaves the wound in a condition which makes healing impossible. And finally this leads on directly to the question—

(4) *How are we, in view of all the above, to account for confidence in the utility of the antiseptic method of treatment?*

We may here begin by bringing out that in all probability the antiseptic method, considered as a method for preventing the importation of foreign germs into the wound, has deserved everything in the way of praise that may have been said of it. For it is no doubt owing to the fact that antiseptic solutions have everywhere been employed for washing out the wounds, that there have not developed in the military hospitals in this war any of those graver forms of infection which in pre-Listerian days never failed to put in an appearance. When, however, we pass from prophylaxis to treatment; and from the consideration of the effects in connexion with the patients, taken as an aggregate, to the effects which manifest themselves in the individual who is under treatment; it is then that we come face to face with the problem as to how it has come about that the obvious non-success of the antiseptic treatment is not generally appreciated. It seems to me that this also must be put down to sophisticated vision and to the effects of education. We must remember that the practitioner of to-day has been educated up to expect to find, within a few hours after washing out an infected wound with antiseptic, as much pus and as many microbes as when he last came to dress it.

We now pass to

TREATMENT BY PHYSIOLOGICAL METHODS.

We shall do well to begin by putting quite away from us the current preconception that to abandon antiseptics would be equivalent to abandoning the programme of killing microbes in the wound. A moment's reflection will show that nature has from the very beginning of things been bringing to bear her own antibacterial agents on infecting microbes; and that we have in antiseptics merely a recent substitute for these. Moreover, the surgeon, in treating wounds, has all along, though not with conscious aim, been bringing the antibacterial agencies of the body to bear on the infecting microbes.

In treating a wound infection by physiological methods we have therefore only to follow the surgeon's lead. But we may hope, as we go along, to improve upon his methods. For we shall fix our attention on the guiding principle which he has missed.

The chief points which the surgeon has insisted upon in connexion with the treatment of infected wounds and tissues are the following.—Where there is an abscess sac, or a closed cavity containing pus, this must be laid open; and an outlet for the discharge must be provided—if possible in the most dependent part. Where an infection has spread diffusely in the tissues free incisions must be made; and where these incisions pass through infiltrated tissues they must be carried from sound skin to sound skin, and all the way down to the healthy structures underneath; and here hot fomentations should afterwards be applied. Lastly—and this is one of the teachings of the present war—when amputating through infected tissues unrestricted drainage must be provided: either by leaving the wound unsutured, or (in cases of gas phlegmon) by reverting to the mediæval method reintroduced by Fitzmaurice-Kelly of cutting the limb squarely across at the same level and dispensing entirely with flaps.[2]

Let me now try to show you that all these procedures—and it will not be necessary to consider them all in detail—will in the ordinary case bring the antibacterial agencies of the body into play. And let me further try to show you that when they fail to do this satisfactorily, they never, even when they accomplish all that the surgeon asks, do any effective good in combating the infection.

I shall begin by considering the rationale of the opening up the abscess sac. The popular explanation accounts for the utility of this procedure by telling us that it provides issue for the infected discharges. But that is quite inadequate. For not only does the operation provide issue for the infected discharges, but when it succeeds it brings about the destruction of the microbes which are embedded in the walls of the abscess sac. In reality it alters the whole situation. In the unopened abscess, the antibacterial agencies of the body are overborne by the mass effect of the infecting microbes. The white blood corpuscles in the abscess sac are paralysed, or killed; and all the antibacterial power of the lymph has gone. In the abscess that has been laid open and emptied, the infected bacteria are overborne by the mass effect exerted by the antibacterial agencies of the body. Fresh antibacterial lymph is streaming in through the walls; and phagocytically active leucocytes are emigrating into the empty cavity. But for all that the infecting bacteria are overborne, the infection is not necessarily extinguished. The laying open of the abscess does not always put everything right. The mechanical conditions may leave much to be desired. It may be necessary to obtain a larger outpouring of lymph to wash the embedded bacteria out of the walls of the wound, and to prevent them accumulating in the abscess cavity and effluent channel. Again the antibacterial agencies of the body may require to be brought into more effective operation. It may be desirable to bring to bear on the microbes both a greater volume of antibacterial lymph and a larger force of phagocytes. Or it may be proper to repress the emigration of leucocytes so as to prevent any breaking down of these in the wound.

Now the supplementary surgical procedures which were enumerated above all contribute, more or less effectively, to the accomplishment of one or other of these ends.

Drainage-tubes are devices for preventing the accumulation of infected discharges. But they do not really keep down bacterial growth in the walls of the abscess cavity. There ought to flow out from a wound not a pus composed of disintegrated leucocytes and microbes, but a lymph which is inimical to microbes and favourable to phagocytic activity; and things do not begin to clear up in a wound till its effluent runs clear.

Free incisions carried down into infiltrated tissues are intended to furnish an ample outlet. But in reality the dimensions of the outlet do not necessarily correspond to the superficial area of the incisions. In point of fact the effective outlet will in infiltrated tissues correspond only to a small section of that area. For the lymph spaces are blocked with leucocytes and fibrinous exudation. And there will, moreover, ooze out from the cut surfaces a highly coagulable lymph which very quickly seals up any open pores.

Hot fomentations, in addition to macerating and bringing away the inflammatory exudate, will induce active hyperæmia, and so increase the outflow of lymph.

Leaving operation wounds unsutured and dispensing with flaps will, as already explained, give unrestricted drainage, so far at least as the mechanical conditions are concerned.

We have now arrived at some sort of a general idea as to what would be embraced under the term "Treatment by Physiological Methods," and we have realised that the empirical procedures of the surgeon furnish us with something to work with and to improve upon.

It will be taking a first step to the improvement of these methods if we draw up for ourselves a complete list of desiderata. We shall in setting these out have to bring them into relation with the actual types of wound infection which come up for treatment.

In reality our infected wounds conform, nearly all of them, to one or other of two types. In the *first* type we have an infection of either the unclothed internal surface of the wound, or of the granulation tissue lining it. Examples of this type of infection are furnished (*a*) by recent projectile wounds whose walls are implanted with microbes; (*b*) by suppurating cavities which have just been opened up and evacuated; and (*c*) by old-standing suppurating wounds which have just been washed out and left clean. In our *second* type of wound we have an infection in a dry and infiltrated wall of an infected cavity and in the tissues contiguous to this.

In the former type of wound infection it would be a desideratum to wash the infecting microbes out of the walls of the wound free from microbes by means of a powerful outflowing current of lymph; and it would be desirable in connexion with this lymph that it should carry in with it into the infected cavity whatever force of phagocytes might be required; that it should furnish a favourable medium for, and directly assist, phagocytosis; that it should repress bacterial growth; and that it should not suffer any sensible diminution of antitryptic power if, after ineffective phagocytosis, a certain number of leucocytes broke down in it.

In the second type of infection, while everything that applies to the first type would apply, it would probably be desirable, as special measures, to repress further emigration of leucocytes, and to render the lymph incoagulable so as to prevent any stanching of the lymph outflow.

For the complete realisation of these desiderata we should require to have at disposition an agency for powerfully increasing the outflow of lymph. (I propose almost immediately to show that we have this at disposal.) Further, it would probably be necessary to have at disposition—but till further research has been carried out it is impossible to speak with certainty on this subject—means for promoting and repressing emigration. And lastly it would almost certainly be necessary to be in a position to increase at need not only the antibacterial power with respect to the infecting microbes, but also its general power of repressing the growth of sero-saprophytes. This, however, will come up for consideration in connexion with treatment by vaccine-therapy.

As just announced, I pass now to consider what agents we have at disposal for increasing the outflow of lymph. In this connexion we have already seen that the lymph flow from the wound can be increased by the application of hot fomentations.

---

[2] THE LANCET, Jan. 2nd, 1915, p. 15.

It can be increased also by introducing ether into the wound—the ether, like the hot fomentations, no doubt acting by inducing active hyperæmia.

But I think that better than either of these, because it is more continuous in its action, and because it renders the lymph incoagulable, and also perhaps because it represses emigration, is the lymphagogic application which I have been recommending now these many years back. This consists of a 5 per cent. solution of common salt, mixed with ½ per cent. of citrate of soda. This brings into play osmotic forces, and "draws" the lymph out of the walls of the wound by a *vis a fronte*. The citrate of soda is added with a view to decalcify and render incoagulable the outflowing lymph.

I may perhaps be allowed to say with regard to this lymphagogic solution, or rather with regard to the simple 5 per cent. salt solution which I find works in most cases equally well, that it has in this war proved itself pre-eminently useful. When brought into application upon a dry and infiltrated wound, or a wound that is foul and covered with slough, it resolves the induration, brings back moisture to the surfaces, and cleans up the wound in a way that no other agent does. Applied in gaseous gangrene in the form of a wet dressing to incisions which have been carried down into infected tissues it causes lymph to pour out of the wounds and arrests the spread of the infection. And again, applied in gaseous gangrene to an amputated stump in cases where it has been necessary to leave infected tissues behind, it reverses the lymph stream and draws out the infected lymph—saving life in almost desperate conditions.

What would be the proper culmination and end to the treatment of wound infections by physiological methods?

We have now arrived at a point when it will be proper to keep our eyes somewhat less closely upon the ground, and to ask ourselves what kind of a coping-stone is to be placed upon our edifice of physiological treatment. For it is clearly unthinkable in connexion with such treatment carried out on scientific lines that it should conduct to nothing better, than to that everlasting dressing and redressing of the wound, into which all antiseptic treatment seems to run out. I am convinced that, when once we shall have learned exactly how to regulate the outflow of lymph, and to control emigration and phagocytosis, it will be practical policy to make an end once for all to a wound infection, and to close up the wound.

Even as we stand at present that seems to me to be to some extent a realisable ideal. While it would lead too far to follow up this question in detail, it will perhaps not be amiss to direct attention to the following points.

It will always and ever be impossible to sterilise a wound within the space of a few minutes. To wash out microbes from the granulation tissue will always take time. And we shall always have to allow time for the leucocyte to find the microbe; and for phagocytosis; and for the digestion of the microbe in the interior of the phagocyte. And again and above all, we shall always have to allow a very large margin of time for the miscarrying of lymph lavage, emigration, phagocytosis, and the intracellular destruction of the microbes, and for the necessary going back over all these processes.

In view of this it will be clear that when we embark upon physiological treatment we ought to carry it out unremittingly. And our treatment will perhaps best take the form of continuous irrigation or continuous baths.

When by these means we think we have rendered our wound sterile or nearly sterile we must in closing up the wound, or giving it an opportunity of healing up under a scab, always proceed by the method of trial and error and provide for the possibility of the microbes again taking the upper hand.

(*To be continued.*)

THE SCOTOMA OF MIGRAINE.

BY F. W. EDRIDGE-GREEN, M.D. DURH., F.R.C.S. ENG.

IT is always interesting to show that some pathological phenomenon is explained by some simple disturbance of a physiological process. I have shown that the foveal region of the retina, which contains only cones, is sensitised from the peripheral portions containing rods. A simple illustration of this will suffice. If on awaking in the morning the eyes be directed to a white ceiling, the central portion of the field of vision appears as a black spot, and light appears to invade this spot from without inwards. On closing the eye again a bluish-violet circle appears at the periphery or middle of the field of vision, contracts, and then, after breaking up into a star-shaped figure and becoming brighter, disappears, to be followed by another contracting circle. If the eye be opened when the star figure has formed in the centre it will appear as a bright rose-coloured star, much brighter than any other part of the field of vision. If, however, we wait till the star has broken up and disappeared before opening the eye it will be found that only a black spot is seen in the centre. I regard these circles as due to the circulation of photo-chemical fluid sensitised by the visual purple over the ends of the cones. It will be seen, therefore, that if there be any disturbance of the circulation of the eye so that this flow of photo-chemical fluid to the fovea be interrupted we should have a central scotoma increasing from within outwards. This is the phenomenon which is experienced in migraine. The varying sensibility of the fovea has always been a puzzle to physiologists. The old view of vision in which the rods and cones are supposed to be directly, or indirectly by means of photo-chemical substances present in them, sensitive to light, is inconceivable. On this view what would be the condition of the cone after light had acted upon it, how would the photo-chemical substances be restored whilst light is still acting on the eye? We know that the cones have no direct blood-supply. There is no evidence that the rods are percipient elements. If, however, we adopt the view that the cones are stimulated by the decomposition of the photo-chemical fluid surrounding them, we have a very simple explanation of vision which accounts for a large number of previously inexplicable facts, as, for instance, that light can impinge upon the fovea without producing any sensation, or that two after-images can change their relative places in the field of vision and become combined into one, the interval between them becoming less and less.

Willesden Green, N.W.

SOME PHYSICAL DEFECTS MET WITH IN THE RAISING OF AN ARMY.

By SIR THOMAS OLIVER, M.D. GLASG., F.R.C.P. LOND.,

HONORARY COLONEL (TYNESIDE SCOTTISH), 20TH BATTALION NORTHUMBERLAND FUSILIERS.

THE present crisis has given some of us the opportunity of coming into direct contact with large numbers of men drawn from various social grades and forms of human activity eager to join the ranks and serve their country. As it is more than likely that many men will yet be required for the army my remarks are not altogether uncalled for. As regards recruiting Newcastle and Tyneside have done well. Between 40,000 and 50,000 men have been given to the navy and the army from this district alone. Until the end of December the Northumberland miners had alone contributed 12,059 men; 31·1 per cent. of the men in this district between the ages of 18 and 38 have enlisted.

My own experience of the subjects later to be dealt with has been gained during the raising of the Tyneside Scottish Brigade. With the assistance of a local committee we succeeded in raising four battalions, each of 1100 men, in the short space of 22 days. The recruits have been drawn mostly from the artisan and labouring classes. Only a few of them have been clerks and shop assistants. Most of them have worked in shipyards, ironworks, and coal-mines. When Lord Kitchener invited us to raise one battalion of Tyneside Scottish he gave permission for men to be taken up to the age of 45 years instead of 38. At the time, this extension of the age-period was a concession of some assistance to us in getting men, men who were seasoned and who looked at life more seriously than those of younger years. Unless, however, careful discrimination is made it is a question whether such a concession is an unmixed benefit. Local industries and their effects upon the men must be considered. Many of the industries of Tyneside make heavy demands upon the physique and enduring powers of the men. They differ entirely from the textile industries and some of the occupations of large towns, in so far as while they stimulate development in early manhood they are hard and somewhat exhausting; they tend to cause premature decay, or at least unfitness to undertake hard muscular work in any other direction than that for which their daily work of 20 to 25 years has trained them. These men can go on doing their ordinary work after the age of 45 quite well, but it is another thing to take them to other kind of work which makes new and engrossing demands upon them, since much of the elasticity of their tissues is gone, and with it the readiness to adapt themselves to other conditions of life and labour. The number of men thus rejected as unfit for military purposes is considerable. It is 30 per cent. It was therefore with knowledge of these facts, based upon experience, that I concurred with General Ternan, Brigadier of the Tyneside Scottish, when he suggested that for men about to be *enlisted for foreign service* it would be better to make the maximum age 38 instead of 45. One of the advantages of having older men in a battalion is that in the billets they exercise an influence for good upon the younger men. They steady their juniors but in long-distance marching, 17–20 miles twice a week, and in regular systematic drill the seniors are more apt to break down. Much of the breakdown would be avoided if the training was gradual and not so accelerated. I cannot be too insistent upon this point.

The disparaging remarks I have made in regard to age and fitness only apply to men who have been exposed to hard physical work, for there are many men who either at, or immediately beyond, the age of 45 are just as good physically as, and who can probably endure more than, men of 25, but they have been drawn from work which has not caused such severe physical strain as the occupations I have referred to. This applies, for example, to the men of the "Scottish Horse" (Lord Tullibardine's) and to "Lovat's Scouts," who have been drawn mostly from the agricultural classes. The extended age-limit, therefore, is a concession to be made use of in the case of well-preserved men whose occupations have not aged them, also where men are required for home defence, and who in this country could probably be transported without great difficulty.

It is interesting to see how the previous occupation of the men has helped them as soldiers. Joiners, carpenters, and builders' labourers have been most useful to the brigade in preparing the ground and in erecting the huts in Alnwick Park. Miners, for example, have shown themselves to be extremely capable of making trenches. Military training, however, soon finds out the weak spots in a man's body, and this leads me to speak especially of coal-miners who as a class suffer much from fractures of bone in close proximity to their joints. Miners who have followed their avocation for many years, working for the greater part of the shift in a stooping position, become weak in the knees. They suffer very frequently, too, from displaced cartilage of the knee-joint. Dr. E. Napier Burnett found that the feet of middle-aged colliers—40 to 45 years of age—readily gave way during military training owing to pain and thickening of the metatarso-phalangeal joint of the great toe.

Complaints are numerous all over the country as to the manner in which the medical examination of recruits has been made. There is not the least doubt that the examinations have not been so systematically and carefully carried out as they ought to have been. This may partly have been owing to the great rush of recruits, but allowing for this there have been such glaring physical defects and deformities overlooked by the doctors that clearly only the most cursory medical examination could have been made. There is no excuse for examiners having passed men totally blind in one eye from cataract, men who have lost the index finger of the right hand, who have lost two fingers of the left hand or two toes, who have hernia, hæmorrhoids, large and readily seen varicose veins, who are flat-footed, or who are the subjects of advanced heart or lung disease. Here is an illustration.

A private, aged 30, who had been training in the south of England, consulted me as he had been discharged from the army as being physically unfit. The man could hardly walk across the floor of my consulting room without experiencing great dyspnœa. His feet and legs were swollen. On exposing the chest the apex of the heart could be readily seen and felt beating 2 inches below and external to the left nipple. On auscultation a loud rough systolic murmur could be heard which the merest tyro in medicine could have detected. The cardiac murmur must have been there at the date of examination, for within four weeks after joining his battalion this man had made his first route march of 14 miles with a 20 minutes' break mid-way. On that occasion it took him all his time to walk into the camp. Shortness of breath developed the same evening or during next day, and in five days afterwards he was discharged as unfit for military service.

This case does not by any means stand alone. In other instances the men had not been stripped sufficiently, otherwise paralysed shoulders and paralysed muscles of arms and forearms would have been detected. The number of men who have been allowed to pass into the army with flat feet and hammer toes is almost incredible.

The object of my remarks is as much as anything to draw the attention of medical examiners to the necessity of exercising greater care than many of them have been doing. Apart from the expense, it lightens the work of future administration. Carelessness on the part of medical examiners has been evident in such a large number of instances that by permitting physically defective men to be attested, fed, uniformed, and drilled, who are obliged to be discharged a few days or weeks after attestation, considerable expense has been incurred to the country, disappointment caused to the rejected men, and through them returning home dissatisfied further recruitment has been made more difficult. It is estimated that the attestation along with the bonus, the clothing, feeding, and subsequent discharge of those unfit for military service has cost the country nearly £2,000,000.

As regards the state of the teeth of recruits, the War Office has made valuable concessions. Bad teeth are so frequently met with among working men that it was clear unless something was done in regard thereto many men otherwise physically fit were being lost to their country's service. Free dental treatment at dental hospitals was a step in the right direction. So far as the Tyneside Scottish battalions are concerned, the arrangement with the hospital worked satisfactorily. The work at the hospital was restricted at first to *extraction*, with or without local anæsthesia as the patient preferred, and to *fillings*. Dentures were subsequently allowed, but these were only given to men of good character and of good physique, men who were likely to appreciate the gift. One drawback to supplying artificial teeth is that if a man at the front is dissatisfied or has a grievance he may throw his dentures away, and, pleading inability to masticate food, he may, when he can ill be spared, have to be sent home.

The importance of testing the eyesight goes without saying, and yet in regard to this there have been several instances of men having been attested with very grave visual defects. Very interesting information has been gained in Newcastle in regard to this subject of eyesight. A large number of our recruits has been drawn from the mining population. It is difficult to give the percentage, but in some of the battalions miners form 60 to 70 per cent. of the men. We were hardly prepared for the large number of cases of nystagmus which developed in the men after they had been in the billets for several days or a few weeks. Sometimes the nystagmus has been of the most pronounced type. There is nothing to indicate that the oscillatory condition of the eyeballs was always present at the primary medical examination. It might have developed as the men passed longer time in the daylight than their work previously allowed them. This, however, cannot be the explanation, otherwise nystagmus would ere this have developed during miners' strikes. So pronounced has been the nystagmus in some of the men, and so deficient their power of vision, that serious accidents have arisen. Many of the men who are the subjects of it have great difficulty in seeing clearly at the time daylight passes into twilight. In one instance a recruit walked into and broke the large plate-glass window of a shop. He did not know that he had reached the window. Where nystagmus has been well developed none of the men have improved rapidly enough under observation and treatment to be retained; they had, therefore, to be dismissed. Where the defect was slight some of the men have been kept for lower forms of administrative work. Nystagmus is a disqualification for military service. The subjects of it cannot even undertake the ordinary physical drills since the rapid movements required, including those of rotation of head and body, aggravate any nystagmus that may be present. Since in many of the men who are affected with it the right eye is worse than the left, the men can only shoot from the left shoulder. Without expressing an opinion as to the disability of associating such men in the trenches and elsewhere with those who fire from the right shoulder, a far more serious aspect of the question relates to sentry duty. As already stated, it is just as evening approaches, when the daylight is fading, that the vision of these men is worst. A sentinel on duty thus affected might, therefore, not through carelessness but disease, endanger not only the lives of the men of a whole battalion but wreck the chances of our troops at a critical moment through not observing the approach of the enemy. I am led to believe that the high percentage of nystagmus met with among North Country coal miners does not equally prevail in those drawn from other parts of the country.

Albuminuria has been found in a small percentage of otherwise apparently healthy recruits after hard physical drill and long route marching.

The small amount of venereal disease among the men of the Tyneside Scottish battalions has been a cause of congratulation. Dr. N. Maclay, who as civil surgeon was in charge for a time of one of the battalions, informs me that it has not been more than 1 to 2 per cent. A similar remark applies to crime. It is only right to say, considering the fact that in Newcastle and district we had a few months ago upwards of 100,000 soldiers suddenly implanted in our midst, that the amount of crime has been extremely small.

As regards inoculation for typhoid fever, the Tyneside Scottish raised no difficulty. Some of the battalions were done to a man without any dissent. At one stage of the proceedings it was thought the preventive measure ran the risk of receiving a check as one of the men died shortly after the inoculation, but fortunately, although the civil medical practitioner who had attended the patient gave a certificate that death was due to (1) typhoid inoculation, (2) pneumonia and heart failure, the necropsy revealed heart disease of long standing, chronic pleurisy, and an alcoholic liver.

Newcastle-upon-Tyne.

ROYAL SOCIETY OF ARTS.—Lectures will be delivered at the Royal Society of Arts, John-street, W.C., on April 26th and May 3rd, 10th, and 17th by Dr. David Somerville, the subject being Foodstuffs. On May 5th Mr. Augustus Vernon Harcourt, D.Sc., F.R.S., will deal with the subjects of Measurement of Efficiency of Domestic Fires and a Simple and Smokeless Grate. The lecture hour on each occasion is 8 P.M.

THE TREATMENT OF GUNSHOT AND SHELL WOUNDS.

WITH SPECIAL REFERENCE TO CARBOLISED GLUCOSE AS A DRESSING.

BY H. BECKWITH WHITEHOUSE, M.S. LOND., F.R.C.S. ENG.,
LATE HUNTERIAN PROFESSOR, ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE character of the wounds received during the present war has given rise to much discussion and criticism of the most appropriate treatment to be adopted. During the early months of the campaign, before the pathology underlying the various lesions had been investigated, treatment was conducted upon established and previously conceived ideas. It was soon noted that such methods had very little practical value in combating the severe sepsis supervening upon trauma produced by modern artillery and rifle fire. It was found that the "first field dressing" was quite powerless to prevent the ingress of pathogenic micro-organisms. The germs had already been inoculated before the dressing was applied. Experiments also proved that the application of pure liquefied carbolic acid to the wounded surfaces was not sufficient to combat those pathogenic organisms carried far into the tissues and quite inaccessible to outward applications. It must then be accepted that the great majority of wounds arriving at the base hospitals from the front are already septic upon arrival. In many cases the sepsis is of a very grave character and varies directly with the nature of the wound, the period of transit, and the treatment that has been adopted during this period.

The second of these factors may be dismissed with the remark that, considering the exigencies of war, the arrangements with regard to the evacuation of wounded from the front to the base appear to be such that very little, if anything, is to be desired.

As to the treatment during the journey from the front and subsequently, research has proved that radical changes are necessary in the methods employed. To these researches the army and the medical profession are indebted to Colonel Sir Almroth Wright. He has proved the absolute inefficiency of antiseptics applied to the large, irregular, and frequently very deep wounds produced by modern missiles.

Lymph Lavage: Employment of Carbolised Glucose.

To those working at the base it was evident quite early in the campaign that the ordinary methods then in use for treating septic wounds were not efficient in obtaining the best results. Wounds did not heal rapidly in spite of daily application of various antiseptic solutions, repeated fomentations, and the like. The importance of obtaining a rapidly healing wound can hardly be overestimated from a military standpoint. In the present campaign the functions of a large base hospital in France are mainly twofold—viz., (1) to cure as quickly as possible those men who can within a reasonably short time be brought to a standard of efficiency; and (2) to render fit to travel those patients whose wounds are too severe to allow early return to the firing line. Added to which, sufficient accommodation must always be available to cope with the sudden and possibly unexpected arrival of large convoys of wounded from the clearing stations and field ambulances. Unless wounds heal rapidly a congestion of cases occurs, due to inability to transfer patients either to England or convalescent camps. Any method, therefore, which favours this end appears deserving of consideration by those engaged in treating the large number of septic wounds continually arriving from the front. Wright has shown that diminution in sepsis can be most readily attained not by the application of bactericidal substances from without, but rather by utilising the antibacterial bodies normally circulating in the blood and lymph. Aerobic and anaerobic organisms are present in the nooks and crannies of wounds in positions quite inaccessible to any antiseptic solution applied from without, but readily destroyed if sufficient bactericidal bodies can be brought into contact with the same by means of the lymph stream. In other words, "lymph lavage" is the all-important factor in the treatment of septic wounds. Wright suggested that this may be established by the application of hypertonic solutions to wound surfaces. He advised the application of a solution of sodium chloride, 5 per cent., with the addition of sodium citrate, 1 per cent., to prevent coagulation of lymph in the tissue interstices.

Adopting Wright's recommendations, I treated a series of shell and gunshot wounds of varying degrees of severity, admitted to No. 8 General Hospital, Rouen, by the application of hypertonic saline solution. The results obtained were sufficiently convincing to prove the correctness of his views. At the same time, the degree of lymph lavage produced by a saline solution was not great, and although sepsis diminished and wounds healed the important factor of time was not sensibly diminished. It appeared to me, therefore, that even better results were possible by employing a solution of greater osmotic power. The substance that occurred to me was glucose. I therefore had a solution of liquid glucose prepared containing sufficient carbolic acid to have a strength of 1 in 80. This solution was applied directly to the wound surfaces and by means of plugs was carried into the recesses of the same. The results quite exceeded my most sanguine expectations. In a few hours sufficient lymph was exuded from each case to saturate the whole of the wool and bandage covering the part. Coincidently the purulent character of the discharge changed, and in a day or two a healthy granulating surface remained. The cases so far treated by carbolised glucose dressings include severe compound fractures and large lacerated wounds of the extremities, some involving the elbow-joint and necessitating excision of the joint. One case of shell wound of the cranium exposing the dura mater and injuring the superior longitudinal sinus was also so treated. All the cases made a rapid recovery and were ready for transfer to England at the end of seven days.

Treatment of Septic Wounds.

The routine which I now adopt in the treatment of all septic wounds may broadly be expressed as follows: (1) Removal of foreign bodies after location by X rays and if anatomically possible; (2) application of efficient drainage by enlargement of the wounds of entry and exit, or by fresh incisions into the tissues if required; (3) removal of as much necrotic and contused tissue and blood clot as possible; (4) application of warm hydrogen peroxide (20 vols.) to the recesses of the wound if anaerobic infection is suspected; and (5) establishment of profuse lymph lavage by the application of a solution of carbolised glucose on white gauze dressing or gauze plugs.

As regards the removal of foreign bodies, it must be remembered that Mauser and shrapnel bullets and fragments of shell are not the only objects that require extraction. Practically 50 per cent. of septic wounds contain more or less large portions of cloth carried deep into the tissues, and easily overlooked unless direct search is made. These fragments of "wardrobe," often extremely foul, are found not only with Mauser and shell wounds where the missile is retained, but also quite frequently in perforating injuries. They are a fertile source of severe and prolonged sepsis, and a danger to the individual until removal is effected. Foreign bodies of this nature are unrecognisable by the X rays, and their frequent presence is one very good reason why all septic wounds and sinuses should be carefully explored. I use the word carefully advisedly. These cases, many of them very serious, should not be regarded as matters of little concern, and any operative interference should only be in the hands of those qualified by practice and experience to conduct such.

Concerning the question of efficient drainage, much depends upon the type of injury. In the case of large lacerated wounds with considerable loss of tissue, practically the whole surface is exposed and no further drainage is required. Care must be taken above all not to bank up such wounds with piles of gauze and wool and so defeat nature's own end. All that is required is a layer of gauze saturated in glucose solution, covered by just sufficient absorbent wool to soak up the very free discharge. Fomentations are the very worst type of dressing to employ in such wounds, especially if backed up with jaconet or batiste. These latter are now entirely absent from my wards, and since they have been discarded a marked improvement has been noted in the condition of the wounds.

Referring to the removal of necrotic and contused tissue and blood clot, it may be argued that the leucocytic zone is broken down and infection implanted upon tissues previously healthy. Experience has shown that this risk is by no means real. In fact, wounds so treated heal more rapidly after removal of all débris and necrotic tissue than if time was expended in waiting for sloughs to separate. In the case of compound fractures some doubt has been expressed as to the advisability of removing loose fragments of bone. In the presence of severe sepsis I unhesitatingly recommend that all such loose fragments be removed at the time that the wound is originally explored. Unless this is done convalescence is delayed and sooner or later the fragments are discharged as foreign bodies or require operative removal for persistent sinuses. In many cases of compound fracture, apart from other considerations, removal of loose portions of bone is required in order to establish free drainage. The fractures examined during the present campaign are in many cases remarkable for the extreme damage done to the bones. The osseous tissue is practically pulverised, and removal of the loose fragments is necessary before efficient drainage is possible. Once a free passage has been prepared for the evacuation of the discharges, all that remains is to establish a free and continuous flow of lymph by means of osmotic power. Glucose answers this requirement in an admirable manner. In the case of deep sinuses and bullet tracks it may be introduced in the form of suppositories containing sodium citrate with a basis of spermaceti or ol. theobrom. On the other hand, for large indolent wound surfaces it may be applied as an ointment containing sodium citrate (1 per cent.) with a lanoline basis. Where possible, such as in fixed hospitals, the best results appear to be obtained by soaking a layer of gauze or wisp of gauze plugging in a saturated solution of glucose containing carbolic acid (1 in 80) and applying it directly to the wound surface. Sufficient wool is added to the dressing to absorb the discharge, and no more. The part should on no account be firmly bandaged. In fact, in a fixed hospital, bandaging unless required for immobilisation purposes in conjunction with splints is best discarded altogether. The dressing is changed as soon as the discharge appears upon the surface of the wool. It may be asked, What is the value of carbolic acid in the dressing? It is added to the glucose solution to destroy those micro-organisms which are present on the surface of the wound and which are brought from the deeper tissues by the free flow of lymph. Its presence appears to prevent all foulness of the discharge and renders the wound and dressing free from odour. In a strength of 1 in 80 it does not damage the tissues, and further does not militate against healing of the wound.

Treatment at Dressing and Clearing Stations.

In conclusion, a few suggestions may be offered as to what can be done at the front and on the lines of communication to diminish the amount of sepsis during transit. Drainage must be established and lymph lavage instituted. At the front elaborate measures are impossible, and the very simplest methods must be employed. If it is impossible to make adequate arrangements for free drainage, at any rate care should be taken that the measures employed do not prevent it. In other words, all dressings and bandages should be applied quite loosely. Men appear to forget that in the case of extremities the limb almost invariably swells during its transit from the front to the next station, and that a bandage that appears properly applied at the dressing station may be an absolute danger if any delay is experienced during transit. Lymph lavage can be promoted by inserting one or more glucose and sodium citrate suppositories into the depths of a wound or along the track of a bullet. These suppositories are cheap, easily carried, and readily applied. In fact, it is much easier to slip one of these into a wound than to apply tinctura iodi with a brush. Finally, when the cases reach a clearing station or fixed station, where more detailed treatment can be employed, each wound should be examined with a view to establishing more efficient drainage if such does not already exist. In the majority of cases, if the part is swollen and œdematous and pyrexia present, it is quite sufficient to enlarge the wound by incision, opening up tracks and carrying a rubber drainage-tube into its depths. A carbolised glucose dressing should then be applied and glucose injected into the deep parts of the wounds. The case may then be transferred to the base hospitals, where facilities are available for meeting all surgical requirements.

If this routine were carried out I feel convinced that very soon there would be a considerable diminution in the number of foul suppurating wounds arriving from the dressing stations and clearing hospitals. Treatment of these septic cases is quite simple if conducted upon a proved physiological basis. It may be summed up in very few words—viz., (1) light bandaging, (2) free drainage, and (3) lymph lavage.

BRAIN ABSCESS IN A CASE OF PARATYPHOID B.

BY R. L. SCOTT, M.B., F.R.C.S.EDIN.,
TEMPORARY LIEUTENANT, R.A.M.C.;
AND
WILLIAM H. JOHNSTON, B.A., M.B. EDIN.,
TEMPORARY LIEUTENANT, R.A.M.C.

THE importance of a more accurate clinical and bacteriological differentiation between diseases of the coli group appears to be amply justified by the findings of the present campaign. Statistics are as yet incomplete, but those we have since the outbreak of hostilities demand a closer investigation of the interesting paratyphoid group. The following case of paratyphoid B., which recently occurred at No. 1 General Hospital, presents a particularly interesting complication.

The patient, aged 21 years, a private, was admitted into No. 1 General Hospital on Feb. 3rd, 1915. He gave a history of feeling ill, with pains in the abdomen, diarrhœa, and headache commencing on Jan. 26th. In addition, he now complained of pains in the back and legs. There were sordes, furred tongue, and characteristic spots on the abdomen, which was tympanitic and tender on palpation. Spleen enlarged. No abnormal signs in lungs and heart. Urine normal. Nothing characteristic in the fæces. Pulse 110. Temperature 103° F. On Feb. 4th a provisional diagnosis of enteric fever was made and the patient was removed to the isolation division of the hospital. He complained of severe pain in the right side of the head and seemed very ill and drowsy. The pulse became dicrotic. The blood was cultivated, but proved to be sterile. No organism of the typhoid group could be isolated from the urine or fæces.

On Feb. 8th the patient developed a hemiplegia of the left arm and leg; his left facial and left hypoglossal nerves were also paralysed. He developed incontinence of urine and fæces. There was no vomiting. No abdominal or cremasteric reflexes could be elicited. His expression was clouded and he became more drowsy, dull, and apathetic. He replied to questions very slowly, thickly, and not immediately, and yawned occasionally. He complained of pain in the right temporal region and at the back of the right ear. Percussion over these areas made him wince. There was no œdema over either mastoid, but tenderness was present over the right mastoid area, especially over the tip. Tenderness was also elicited over and down the right side of the neck in line with the internal jugular. On examination of the ears, beyond a slightly injected Shrapnell's membrane and a little injection around the handle of the malleus on the right side, nothing of note was found. There were no signs of past or present middle-ear disease. Nose and throat examination revealed nothing. Examination of the fundi was difficult, but the edges of the right disc appeared rather hyperæmic and indistinct. The pulse was no longer dicrotic, but full and slow; the temperature, on the other hand, remained high. This lack of conformity was very obvious on the chart.

A diagnosis of right temporo-sphenoidal abscess was made, and on the strength of the definite tenderness over the right mastoid it was decided to explore this region first, and if nothing should be found to trephine over the usual site. Unfortunately the patient collapsed under the anæsthetic before any operative procedure was begun. It was deemed inadvisable to proceed any further. Lumbar puncture was performed and 10 c.c. of clear cerebro-spinal fluid were withdrawn under no excess of pressure; cultivations of it were sterile. The subsequent history of the case was characteristic of a gradually increasing intracranial pressure. Coma and full stertor developed on Feb. 12th and death supervened the next morning.

Necropsy.—Post-mortem examination revealed the following:—The spleen, somewhat enlarged, was attached by recent adhesions to the diaphragm. The upper pole showed purulent softening. The walls of the greater part of the ileum were atrophic, thin, and transparent, and in parts intensely hyperæmic. There was a uniform enlargement of the corresponding mesenteric glands, those in the ileocæcal angle being most markedly affected. In that area individual glands were as large as beans; some were fused by an inflammatory œdema and showed on section central necrosis. The serous aspect of the cæcum presented a picture of intense hyperæmia with numerous adhesions. The lymphadenoid tissue of the ileum appeared to be but slightly affected, considering the amount and severity of the ulceration. The appearance suggested a general hypoplasia of the lymphadenoid tissue. Ulceration was confined to the lower two feet of the ileum and to the adjacent portion of the cæcum. The ulcers, irregularly placed, were pitted, varying in size from a pea to a shilling, with sinuous edges raised towards the mucous coat, well marked and slightly indurated. Resting on the muscularis mucosæ the floor was granular and of the usual striated appearance. The opposed area of serous surface showed neither localised peritonitis nor adhesions, and there was an entire absence of subserous follicles suggestive of tuberculous infection. The ulcers did not tend to encircle the gut, but had a follicular distribution, apparently with no definite relation to the lymphadenoid tissue. They suggested an acute process and appeared of recent formation. The largest, occurring near the ileo-cæcal valve, measured three-quarters of an inch across. There appeared a marked dissimilarity from the typical lesions of both enteric fever and tuberculosis.

The vessels of the dura mater were unduly injected. Beyond a slight engorgement of the capillaries leading down from the anterior part of the Sylvian fissure, the arachno-pial membrane was normal. There was a considerable œdema of the right brain well seen in the frontal and temporo-sphenoidal lobes. The right hemisphere was much larger than the left, overlapping it along the longitudinal fissure and to a certain extent displacing it. On section, an abscess about the size of a shilling was found embedded in the outer and posterior aspect of the right optic thalamus. The adjacent limb of the right internal capsule was partially destroyed. Pigmentation and encapsulisation were absent. The œdema on section was very obvious. There were the usual displacement and distortion of mesial structures, the fornix being pushed aside and the left ventricle being flattened. The abscess had not ruptured into the right ventricle.

For the following report we are indebted to Lieutenant M. K. Acheson, bacteriologist, No. 1 General Hospital. "Several attempts were made with negative results during life to isolate from the blood, fæces, urine, and cerebro-spinal fluid the organism causing the patient's illness. At the post-mortem examination a non-motile, Gram-negative bacillus was obtained in pure culture from the spleen. In bile salt glucose and mannite it gave acid and gas; no change took place in bile salt lactose. The Bordet-Durham reaction was tried with results shown in the following table:—

—	Dilution.				
	1 in 40.	1 in 80.	1 in 160.	1 in 320.	1 in 1000.
Typhoid	Complete.	Partial.	Partial.	Negative.	Negative.
Paratyphoid A.	Almost complete.	,,	Very slight.	,,	,,
Paratyphoid B.	Complete.	Complete.	Partial.	Partial.	Partial.

The Bordet-Durham reaction for Gaertner could not be performed as no agglutinating serum was available.

As the brain was at once placed in formalin solution no bacillus could be isolated from the abscess when sections were cut. It is unfortunate that the Bordet-Durham reaction for Gaertner could not be performed, but the evidence, clinically and bacteriologically, seemed fairly conclusive that the disease was due to the bacillus paratyphoid B."

A CASE OF HYSTERO-CATALEPSY.[1]

BY LIONEL A. WEATHERLY, M.D. ABERD.

THE following case is interesting on account of its rarity, the difficulty of early diagnosis and prognosis, and the favourable result after the case had looked absolutely hopeless. Such a case is mentioned in no English text-books that I have consulted, and leading psychologists and neurologists have written me that they have had no similar case in their practice. I saw the patient in consultation with Mr. Maitland Scott at a nursing home on July 14th, 1914, and at his and the mother's request she was removed to my care on the same day.

The patient was a spinster aged 35, but looked much younger. She came of neurotic parents. A brother was neurotic. The mother was always delicate and within the year had had a paralytic seizure. The patient had always lived with her mother and had been her constant companion. At the age of 17 she had a nervous breakdown and had been sent from home for a short time, but soon recovered. Some six months before admission she had been in constant attendance on her mother by day and night, much against the wishes of her medical attendant, Mr. Scott. The mother was most exacting, never liking the daughter to be out of her sight, and she was getting no sleep at night and no change by day. A few weeks before I saw her she had been so unwell and run down that she was sent away for a change with a companion. During this period her behaviour was somewhat strange. At the last place they stayed she was lost for a whole day, and when found could give no rational account of what she had been doing or her reason for absenting herself. She was then brought to Bournemouth to a nursing home. There was no history of masturbation.

I saw the patient on the morning of July 14th in consultation with Mr. Scott. She was laughing and singing; we had great difficulty in getting her to answer any direct question coherently. There was considerable mental excitement and restlessness and confusion of ideas. She had a typical hysterical appearance, with considerable tremor of eyelids. Reflexes were all exaggerated. Powers of coördination were normal. I pronounced the case as one of hysteria major due to stress and anxiety. Catamenia had been absent for some two months. As the nursing home could not keep her there because she was disturbing some surgical cases by her singing, and as she consented to come under my care, she was admitted into my house on the same evening.

On admission she was hysterically excited, with a very weak pulse and definitely anæmic. Isolation from friends and relations was at once agreed upon. For a few days she was quieter at times and spoke quite sensibly to her nurses and lady companion, talking about events some weeks previous to her leaving home, but seemingly had no recollection of more recent events. At other times she would only laugh and repeat questions without any attempt to answer them. She took her nourishment well, and had very fairly good nights with ʒi doses of compound cerebral sedative (Parke Davis), by day taking an iron tonic with valerian and nux vomica. In about 10 days' time some stereotyped movements of the arms and muscles of the face began, and the eyes were either wide open or tightly closed. The muscular tension in these movements was not always very marked at first and rigidity would after a short time lessen and the limbs could be easily moved (flexibilitas cerea). On August 1st the patient became worse. Some trismus set in. Great difficulty at times in feeding in consequence of violent laryngeal spasm. A rash now appeared on the arms, chest, and legs. There was no rise of temperature. The rash had the appearance of measles and urticaria and lasted 18 days. It was evidently trophic and gradually increased, and the fingers and toes had a myxœdematous aspect. Suprarenal extract (B. & W.), 5 gr. doses, was given by the mouth or rectum three times a day, and the rash gradually disappeared, but great desquamation followed.

During the period from August 1st to 18th she had several trance-like attacks, in which for some hours all reflexes were absent, including the conjunctival reflex. Prior to this trance condition there would be great rigidity of the limbs, the head thrown backwards, and the jaws either tightly closed or widely opened. After about an hour the rigidity would lessen, but the trance-like condition remained for some hours. Definite refusal of food now took place. Any attempt at tube-feeding by the nose or mouth was rendered impossible as violent spasms set in, and the patient almost collapsed. Rectal feeding was resorted to—beef enules, champagne and eggs, brandy and white of egg, &c. The pulse could hardly be felt or counted. Pituitary gland extract was injected hypodermically, and after each such injection the pulse began slightly to improve. This was alternated with hypodermic injections of 1/30 gr. strychnine. Mr. Scott saw the patient with me constantly, and I was with her several times in the night. Her relatives were summoned and death was expected every hour. She was greatly emaciated and almost unconscious. On the eighth day of rectal feeding the rectum no longer retained what was injected, and for 24 hours glucose was the only thing that could be retained, given in small doses.

On Sept. 3rd the patient became rather more conscious, and small doses of Valentine's meat juice and Brand's essence of beef were swallowed.

---

[1] Read before the Bournemouth Medical Society.

Gradually more nourishment was taken. Virol, cod-liver oil and malt, and a preparation of iron were now able to be administered, and she gradually improved physically, but for some days she had a return of the stereotyped movements of the hands and arms, and she did not recognise her relatives. She gradually improved, and by the end of September catamenia appeared, she became much more rational, took plenty of nourishment, and in about ten days' time she was able to join our family circle, and took short walks, played games, read, and made a complete recovery, and was discharged on Nov. 3rd.

Since then, by my advice, the patient has had a companion, has not been so constantly with her mother, and has been out much more and to places of amusement and has kept quite well, with the exception of occasional trophic skin affections, which Mr. Scott tells me have cleared up under thyroid or suprarenal extract.

I think I am justified in calling this a case of hystero-catalepsy. When the katatonic symptoms commenced I rather suspected one had to deal with a case of dementia præcox, but her age and some of her symptoms were, to my mind, against this, and I think the marked hysterical element was proved by the more or less sudden improvement and ultimate recovery after being at death's door. It will, of course, be interesting to know the further history of her condition, as cases are on record of recoverable dementia præcox, with an almost inevitable relapse.

Bournemouth.

THE X RAY THEATRE IN WAR HOSPITALS.

By JOHN R. CALDWELL, M.B., Ch.B. St. And.,
LIEUTENANT, ROYAL ARMY MEDICAL CORPS.

It is the experience of most who have to deal with the extraction of foreign bodies from the tissues that, in spite of the most accurate localisation, time and time again there are the most mortifying failures. The early realisation of this prompted us, at the Baltic and Corn Exchange Hospital, Ecole Sophie Berthelot, Calais, to seek for some method which afforded more direct guidance, and to this end we experimented for a time with the electric probe; but after five months of experience of the removal of foreign bodies, directly under the X rays, we venture to plead for the more routine adoption of a method which has afforded us so much satisfaction.

There are two chief reasons why we plead for the installation of an X ray theatre in all large war hospitals. First, the speed with which extractions can be performed—a factor of importance both in that the maximum of cases can be done in the minimum of time, and in that prolonged anæsthesia is avoided for the patient; and, secondly, the minimum of damage is done to the tissues. Over and over again we have had old, healed cases here for extraction, showing most extensive scars, souvenirs of prolonged search, in which we were able to extract the foreign body *viâ* incisions incomparably smaller than their less fortunate predecessors. It is not our intention to minimise the value of accurate localisation, for that, of course, with this method is still necessary, especially when the trunk or head is involved. The X ray room here is equipped exactly as an operating theatre, but a few points may be worthy of note regarding technique and the general method of working in the theatre. The apparatus employed is by Dean, of London, and has given complete satisfaction. The table employed is three feet broad, with a movable tube box underneath, and the top used for operating is an extra-broad canvas stretcher. On this table it is possible, with the guidance of the rays, to operate on almost any part of the body. In place of mackintosh sheeting we employ jaconet, as the former is too opaque for general use (indeed, it acts as a fluorescent screen). It is obvious that the surgeon must always stand at the same side of the table, otherwise the proximity of the high-tension wires might prove annoying; but if the induction coil be on wheels, it is possible for the assistant to stand on the opposite side, the high-tension wires being made to approach the table obliquely from the opposite end. As assistance is not necessary during the actual extraction, he can stand aside while the apparatus is working. For the protection of the operator's hands we use here extra-thick rubber gloves; if more protection is desired, a thin sheet of aluminium may be placed between the tube and the patient.

The lighting of the theatre was at first very troublesome, the ideal light for the X ray room being subdued, while the reverse is true of the operating theatre. This difficulty we have overcome by employing an old automobile headlight over the table. A 100 candle-power electric lamp is placed behind the condenser, thereby concentrating the light only on the area of operation, the rest of the room being in comparative darkness. This permits careful dissections to be made when necessary, the eyes retaining that acuity so necessary for the actual extraction.

Regarding the administration of anæsthetics it is sometimes necessary for this is to be done for a time in the dark; the anæsthetist is equipped with a covered lamp, controlled by an ordinary electric bell push, and this flashed occasionally and working through a small diaphragm affords him sufficient light without interfering with the course of the operation. It is often necessary for anæsthetics to be administered with the patient in the prone position, but as in most cases the operation is a rapid one there has never been any trouble.

All cases admitted here are subjected to a preliminary X ray examination, and if a foreign body is present it is localised with a thoroughness which varies with the part involved. Should the trunk, the head, or the neck be implicated stereoscopic radiograms are taken. For the extremities all that is usually necessary is to determine roughly by moving the tube the relationship of the foreign body to neighbouring bony structures. Each case, however, must be judged on its own merits.

To facilitate description we may roughly divide cases to be treated into two great classes: (1) old and healed; and (2) recent and septic. In the old and healed the preparation is as for an ordinary operation; the towels are applied in the usual fashion, but we might add that it is advisable to clip them firmly to the skin, so that in the darkness they may retain their position. A towel is set aside for the screen of sufficient size to cover its under surface completely with a margin all around of about 2 inches. This is laid over the cleansed area and the screen is placed in position by the theatre orderly. The assistant now clips on the towel at the four corners, and for this purpose we employ Dieffenbach's bull-dog forceps. Before the actual commencement of the operation the X ray tube is brought into the vicinity of the part involved, and with the orderly supporting the screen the rays are turned on and the lights off. The foreign body is now accurately "centred," and to effect this a small diaphragm is employed. The movements of the tube box can be accomplished with the operator's foot, and these are rendered easier if a toecap to receive the point of the boot be fixed to the front of the box. The point of a pair of Spencer Wells forceps is now laid on the skin so that it coincides with the shadow on the screen. The light is now turned on and the screen removed. With due regard to anatomical considerations the incision is made, not necessarily immediately over the foreign body, for, indeed, an oblique approach is often easier. The skin incision should be fairly free, and when the muscles have been exposed blunt dissection can be employed. No violence in the extraction is permissible, and should the foreign body be in the vicinity of important structures free and careful dissection in a good light is demanded, the operation being merely controlled by occasional reference to the screen. The forceps employed here for actually extracting foreign bodies are usually Kocher's or long Spencer Wells's. As a guide to the correct estimation of the depth of the foreign body it is extremely useful, while the forceps are approaching to move the tube box from side to side with the foot. The relative movement of the foreign body and the point of the forceps indicates their distance apart; for example, if the ball apparently moves somewhat faster than the point of the forceps, the ball lies somewhat deeper. With experience it is scarcely ever necessary to move the tube, more particularly in the case of the extremities, for here a slight rotatory movement of the part supplies the necessary information. The extraction having been performed, the wound is sutured in the ordinary way.

In septic cases, where a sinus exists, the preliminary cleansing of the part and of the sinus is of the utmost importance. For this purpose we employ a triple irrigating apparatus; three irrigators mounted on a stand are connected so that each in turn may be made to discharge *viâ* one cannula.

The solutions employed are: (1) Biniodide of mercury (1 in 1000); (2) carbolic acid (1 in 40); and (3) hydrogen peroxide (1 in 3). The wound is copiously irrigated with these one after the other. This treatment may seem drastic, but is no more than is merited by the frightful septicity with which we so frequently have to deal. The actual extraction of the foreign body is now performed, but here free incisions are very desirable. It is usual to approach the foreign body by an incision which will, by reason of a dependent situation, afford the best drainage possible. In more quiescent cases an approach *viâ* the sinus is frequently sufficient. It is often of value to leave the forceps and the foreign body *in situ*, and enlarge the tract freely before extracting; in this way foreign matters, such as cloth, &c., perhaps of greater importance even than shrapnel and bullet, can be in many cases removed.

As indicating the general applicability of the method, we may mention that with the guidance of the rays we have removed foreign bodies from the posterior mediastinum and from the spheno-maxillary fossa; then there was a pelvic case in which two previous abortive efforts had been made to extract a bullet. In this case we successfully removed the bullet interior from the region of the great sacro-sciatic ligament and the mantle of the same bullet from behind the neck of the femur. Foreign bodies in the neighbourhood of the spine and in medulla of bones have likewise been removed with a success which is all the more gratifying as many of these cases showed evidence of previous attempts. In multiple shell wounds this method of treatment gives much satisfaction; in these cases each wound in itself seems trifling, but the sum total of upwards of six suppurating foci induces such a toxæmic state that prolonged anæsthesia and much interference are very undesirable. We prefer also to operate on compound fractures on the X ray table, as the steps of the operation from start to finish can be controlled and guided by reference to the screen. The value of the method is unquestionable, and while we cannot claim for it originality, we are not aware that it has become a routine method of treatment in any other hospital. With a little experience it becomes possible to remove minute fragments which in the ordinary way would necessitate frightful mutilation.

In conclusion, I wish to acknowledge my indebtedness to Mr. C. M. Hewer, surgeon to the hospital, for his invaluable aid in meeting the many difficulties which arose in the evolution of the X ray theatre.

A RE-INVESTIGATION ON THE NATURE OF THE CELLULAR ELEMENTS PRESENT IN MILK.*

BY R. TANNER HEWLETT, M.D. LOND., F.R.C.P. LOND., D.P.H.,
PROFESSOR OF BACTERIOLOGY IN THE UNIVERSITY OF LONDON;
AND
CECIL REVIS, A.C.G.I.,
CHIEF CHEMIST TO MESSRS. WELFORD AND SONS, LIMITED, LONDON.

IN a series of papers Hewlett, Villar, and Revis[1] recorded the results of investigations on the nature of the cellular elements present in milk. It was shown that cells of various kinds are always present in the milk of perfectly healthy cows, sometimes in enormous numbers, and that no reason could be assigned for the considerable variation in the number of the cells which occurs in the milk of different cows. A preliminary classification of these cells was formulated, and the opinion was expressed that the vast majority of them are not leucocytes, and that the "multinucleated cells" which are frequently present in considerable numbers and have a superficial resemblance to polymorphonuclear leucocytes are for the most part the "germinal cells" of Winkler derived from the epithelial layer of the glandular tissue of the udder and are embryonic cells which develop into epithelial cells.

Breed[2] has recently again stated that these cells are polymorphonuclear leucocytes derived from the blood, and asserts that the evidence formerly adduced by Hewlett, Villar, and Revis is not convincing. As, however, Breed produces no evidence at all in support of his statement, and also having regard to the importance of the subject from the public health point of view, we have considered it advisable to re-investigate the nature of the cellular elements present in milk, to revise their classification, and to attempt to determine the factors which influence their number in the milk of different cows.

---

* This investigation has been carried out in the Bacteriological Laboratories of King's College, London, and of Messrs. Welford and Sons, with the aid of a grant from the Medical Research Committee.

[1] Journal of Hygiene, ix., p. 271; x., p. 56; xi., p. 97; xiii., p. 87 (Bibliography).

[2] New York Experiment Station, Bulletin 380, 1914.

With the object of elucidating the nature of the cells and to revise their classification a large number of trials of various methods of preparing, fixing, and staining films has been made, and it is proposed first to detail the results of this part of the investigation.

Obtaining the Cells.

The cells must be obtained by centrifuging the milk, but it is found that the number of cells thus obtained falls far short of the actual number which deposit after a preliminary treatment of the milk. This preliminary treatment may consist either in warming the milk to 60°–70° C. for 10 minutes or by the addition of a small quantity (0·5 per cent.) of formalin to the milk and allowing the mixture to stand for 24 hours before rotating. The latter was the method adopted in our previous investigations, but the question arises whether some alteration of the cells is not produced thereby. We have made comparative examinations of the cells obtained from milk with and without the addition of formalin, and there is no doubt that even the small quantity of formalin formerly employed does sometimes cause decided contraction of the cells. We have therefore in the following investigation discarded the use of formalin. We find also that a considerable proportion of the cells, and in particular that variety of them which we have provisionally named the "multinucleated," are carried up in the cream-layer, and if the cream-layer be broken up and the milk rotated again, a further yield of cells is obtained; but the process must be repeated three or four times (the breaking up of the cream-layer and subsequent rotation) if even a majority of the cells is to be obtained in the deposit.

Preparation of the Films.

After the deposit of cells has been obtained by centrifuging, they need to be washed so as, so far as possible, to remove the milk and fat admixed with them. The supernatant milk is decanted from the deposit of cells and the fat wiped out of the tube. The cells are then washed. We naturally at first employed physiological salt solution for this purpose, but a study of the results so obtained undoubtedly points to the conclusion that some alteration and distortion of the cells occurs when the film is made and allowed to dry, probably from the concentration of the salt which must inevitably take place as the water evaporates.

As the shape of the cells will be materially affected by the tonicity of the fluid in which they are placed, we were at first inclined to believe that the osmotic pressure of ordinary physiological salt solution was different from that of the milk in which the cells at first find themselves. From the freezing point of milk it may be deduced that its osmotic pressure corresponds to that of a saline solution of 0·9 per cent. concentration. Experiments were therefore made with solutions of sodium chloride of 0·7, 0·8, 0·9, and 1·0 per cent. concentrations, but there appeared to be no appreciable difference in the resulting film. The same distortion or alteration was still noticeable. It was then established that the salt solution in itself had no such influence, as, if the deposit after washing with salt solution was then washed with ox serum (see below) the cells were normal in aspect. It seemed, therefore, that the drying in films was really responsible for the alteration, though it is noteworthy that the tendency is rather towards an expansion of the cell than a contraction, as would be expected in a solution which was rapidly concentrating.

Another modification employed for washing was an alkaline physiological salt solution. Sodium carbonate (Na_2CO_3) was used for this purpose, so that the final alkalinity corresponded to $N/35$ Na_2CO_3 (which is approximately that which obtains in blood serum, according to Wright) and the Na-ion concentration was made approximately equal to 0·9 per cent. NaCl. Other modifications of the wash-liquid were (*a*) solution of egg albumin adjusted by the addition of distilled water to 7·25 per cent. of protein, so as to correspond with the protein content of ox serum; (*b*) egg albumin and sodium chloride, so as to contain 7·25 per cent. of protein and a Na-ion concentration equal to that of 0·9 per cent. solution of sodium chloride; and (*c*) ox serum, both unheated and heated to 56° C. for half an hour. None of these presents any special advantage with the exception of ox serum. We find that washing with heated ox serum gives undoubtedly the best results, causing the least contraction of the cells of any washing agent employed. The aspect of the cells obtained from the same milk, washed in the one case with saline and in the other with ox serum, is entirely different, and the cells would scarcely be recognised as of similar origin. The effect of saline is most marked on nuclear structures.

Preparation of the Films.

The cellular deposit after washing and centrifuging is deposited on a clean slide and spread with a glass rod so as to form a thin even film. This is allowed to dry in the air or by warming to 37° C., and the slide with the dry film upon it is then immersed in a mixture of equal parts of alcohol and ether, to remove the fat, for from half an hour to several hours; it is then ready for staining.

Staining the Film.

A number of different staining methods has been tried, the stains employed being Jenner's stain, Leishman's stain, Pappenheim's stain, Giemsa stain (Revis's method [3]), Giemsa stain (Coles's method [4]), Ehrlich's tri-acid stain, hæmatoxylin and eosin, and the May-Grünwald stain. Of all these, the May-Grünwald stain [5] undoubtedly gives the best results. This is carried out as follows: One tablet of the May-Grünwald stain is dissolved in 100 c.c. of pure methyl alcohol (this solution keeps well). Of this solution, 0·3 c.c. is dropped on the film and allowed to act for one to two minutes, then 0·9 c.c. of specially distilled water is dropped on and is allowed to act for three to six minutes. The film is finally washed in distilled water and dried in the blood-heat incubator. In order to prevent the stain running all over the slide it is useful to make a streak at either end of the film with a soft paraffin mixture composed of vaseline 75 parts and paraffin wax 25 parts, and melted in hot water for use.

We are now trying the method described by Scott for blood films,[6] in which the films are not allowed to dry but are fixed with formalin vapour and the staining is carried out on the wet film, and anticipate that it may give still better results. Undoubtedly the nuclear structure revealed by this method is very different and much more complex than that brought out by the other methods.

---

[3] Journal of Hygiene 1910, vol. x., p 83.

[4] See Hewlett's Manual of Bacteriology, fifth edition, 1914, p. 525.

[5] The May-Grünwald stain is made as follows: 100 c.c. of a 1 per cent. solution of eosin are mixed with 100 c.c. of a solution of methylene blue and allowed to stand 24 hours. The precipitate is washed with water and dried and made up into tablets of 0·25 gramme each.

[6] Journal of Pathology and Bacteriology, 1901, vol. vii., p. 133.

A point of importance, and one which perhaps has not received sufficient attention, is that the aspect of the cells differs considerably according to the staining method employed. This applies not only to the cells of milk, but also to the leucocytes of ox blood (which we are also studying) which we have employed to control our methods. The actual tint of the various structures is also markedly affected by the reaction of the fluid used to wash the deposit in, so that films of cells washed in saline showed very different results from those washed in ox serum. It is quite certain that some method of at once hardening the cell wall in order to obviate distortion and disruption is essential to the proper study of these cells. It is not improbable that the cells as they appear in ordinary films are quite different in appearance from that which they really possess. For this reason the method of Scott, though somewhat more difficult of application than ordinary methods, has manifest advantages. The statement commonly made that the cells of milk stain well and naturally with ordinary blood stains is, in our experience, quite erroneous.

Influence of "Keeping" on the Cells.

The cells present in milk may obviously either be "recent" or may have gained access to the milk from the period immediately succeeding the last previous milking. The question arises, Will such a sojourn in the milk alter these cells? It is difficult definitely to answer this question. We know that leucocytes may be kept in physiological salt solution apparently unaltered for many hours, and we find that ox leucocytes added to milk are apparently unaltered after a sojourn of 24 hours at room temperature. Similarly, the cells of milk examined immediately after milking and again examined after the same milk has been kept at room temperature for 24 hours show little or no difference. The probability is therefore that the majority of the cells present in milk undergo little or no alteration during the period the milk remains in the udder.

URINARY CALCULUS IN THE PELVIC PORTION OF THE URETER.

BY JOSEPH E. ADAMS, M.S. LOND., F.R.C.S. ENG.,
SURGEON IN CHARGE OF OUT-PATIENTS, ST. THOMAS'S HOSPITAL, ETC.

CASES of calculus impacted in the ureter are of interest from the diagnostic point of view, especially when the stone lies in the right ureter, for in whichever portion it is situated the resemblance of the symptoms to those of appendicitis may easily lead to error. In the present paper I propose to call attention to some points in the differential diagnosis of calculi in the pelvic portion of the ureter and to describe what I consider to be the best route for the removal of such impacted stones.

The three common situations in which calculi become arrested in their descent from kidney to bladder is: (1) At the junction of the renal pelvis and ureter; (2) in the abdominal portion of the ureter, including that part which crosses the brim of the true pelvis; and (3) in the pelvic portion of the ureter. The second is the least common, the first can hardly be distinguished from calculus in the kidney itself, while the third gives rise to symptoms of a most variable nature. It is well known that calculi may remain impacted in the ureter for a considerable time, giving rise to no symptoms when once they have actually come to rest unless the intermittent obstruction which they cause leads to either hydro- or pyo-nephrosis. On the other hand, even stationary calculi may give rise to attacks of pain closely resembling typical renal colic associated with hæmaturia.

Diagnosis.

Most surgeons have knowledge of cases where appendicectomy has been followed by the passage of a urinary calculus per urethram, and of instances of obscure abdominal pain where a similar natural relief of all symptoms has occurred. Such events, whilst satisfactory to the patient, should lead to humility in the surgeon and a determination not to neglect the aid of skiagraphy in doubtful cases. With regard to calculi impacted in the last few inches of the ureter, Thomson Walker[1] states that symptoms of bladder irritation are prominent features, and that there is frequency of micturition with pain along the urethra to the end of the penis; also that genital symptoms may exist, such as painful emissions, hæmospermia, and testicular pain. The patient may complain of pain in the rectum, aggravated by defæcation. Undoubtedly the most constant symptom is pain; abdominal pain, pelvic pain, renal or ureteral colic may be associated with a calculus which has come to rest even in the pelvic portion of the ureter, and the most usual history is of severe attacks of pain in the lumbar region in the past and dull gnawing pain in the lower abdomen in the present history of illness. It is not uncommon for a fixed pelvic calculus to cause pain starting in the loin and extending to the hypogastrium. If definite attacks of pain occur they are usually accompanied by vomiting, sweating, and hæmaturia, but the last symptom is the least constant and may be observed only once or twice even where the attacks are numerous. Rest in bed frequently fails to give immunity against these attacks, as it does in ordinary renal colic. Some fever is apt to be present. As regards urinary symptoms, frequency is the most common, and a careful examination shortly after any acute attack of pain will usually reveal the presence of a trace of albumin and possibly some pus cells; hæmaturia, as already mentioned, occurs in some acute attacks. Tenderness and rigidity on palpation are not uncommon both in the lumbar region and the hypogastrium, even when the stone is impacted close to the bladder. The rigidity, of course, is rarely of the same degree as that found in peritoneal lesions. Hydronephrotic symptoms are comparatively rare, but if they are present they dominate the clinical picture, and before operation the actual cause of such hydronephrosis may not be suspected. The ultimate diagnosis usually rests with the result of X ray examination although it may be possible in children to palpate a calculus in the pelvic portion of the ureter by rectal examination, or by the vagina in the female. When the stone lies impacted in the ureter behind the bladder wall cystoscopic examination is usually negative as regards the appearance of the ureteric orifices, but the passage of a ureteric bougie may be arrested, and this observation combined with skiagraphy is most useful in proving the presence of a calculus and the fact that it lies in the course of the ureter. The necessity for such catheterisation of the ureters exists in cases where shadows of an uncertain character are seen on the skiagraphic plate, and the most frequent sources of error are fæcal matter, calcified glands, and phleboliths; the last named most frequently give rise to doubt because they are quite common in the pelvis and not infrequently lie about the line of the ureter, and in size they may correspond to such an impacted calculus. Apart from the need for combined catheterisation of the ureter and skiagraphy it should be borne in mind that calculi are usually elongated or bean-shaped, and nearly always present one pointed extremity, due to the wearing away of the lower end of the calculus in most cases, whereas phleboliths are spherical, and I think I am right in saying they are never shaped like a bean with one pointed extremity.

---

[1] Choyce's System of Surgery, 1912.

The reports on the skiagrams of three cases recently under my care may be of interest. They were all taken by Mr. A. D. Reid, radiographer to St. Thomas's Hospital, and his reports were as follows:—

CASE 1.—Male, aged 36 years. Two years' history. "Shadow present. Probably calculus in lower end of right ureter."

CASE 2.—Female, aged 24 years. Six weeks' history of recurrent pain. A calculus had been removed previously from the left ureter. "Kidney region *nil.* Shadow of calculus in lower end of the ureter, or possibly a phlebolith." Both a phlebolith and a calculus were found at operation.

CASE 3.—Male, aged 9 years. Two and a half years' history. "Shadow in upper part of bladder region. Probably calculus incarcerated in bladder wall." In this case the calculus had been felt on digital examination of the rectum by my colleague, Dr. C. R. Box.

In these cases a more or less accurate diagnosis was made, but required X ray examination to confirm it. In the first case the calculus was thought to be renal in position, in the last the possibility of appendicitis was very strong; in the second case it appeared clear that there was a local recurrence. The first case illustrates the importance of skiagraphy applied to the whole urinary tract in cases of suspected calculus.

Operative Treatment.

In those cases where palliative measures fail and there is no sign of the calculus descending to the bladder, when it may be crushed by the surgeon or passed by the patient, it is important not to delay operation lest gross changes take place in the kidney as the result of back pressure. In all these cases I operated by a suprapubic route, which I have since seen advocated by Judd.[2] It appears to me to be much the best method of reaching the pelvic portion of the ureter, and it has the great advantage of being almost a bloodless operation. The details are as follows. The bladder being distended with fluid and the table elevated so that the patient is placed in a moderately high Trendelenburg position, the usual median incision is made as for suprapubic cystotomy. As soon as the vascular outer coat of the bladder is thoroughly exposed the knife is laid aside and with a gauze pad the peritoneum is swept away from the upper and back part of the bladder. Two silk guides are then passed through the muscular coats of the bladder, which should be emptied of its fluid. The line of cleavage can then be followed by pulling the bladder up towards the lower angle of the wound and pushing the cellular subperitoneal tissue towards the diaphragm; in this way the ureter of either side can easily be found covered by only a small amount of connective tissue, and if a calculus be present and the ureter dilated above this it may be exposed in a few minutes. Some radicles of the vesical veins will be exposed, but in my experience it is rarely necessary to tie any blood-vessels. When the ureter has been identified by its position, its course, and by the presence of a calculus within it the simplest plan is to pass a couple of catgut stitches through its outer coats and pull it up towards the surface of the wound, but it is not desirable to bare any considerable length of ureter, nor is it necessary to do so. A small slit in the dilated ureter will enable quite a large calculus to be removed with narrow-bladed forceps, and the incision can then be closed by fine catgut at right angles to the long axis of the ureter. Some surgeons advise that such ureteric wounds should not be sutured, but I have found it quite easy to do and have had no trouble with leakage after operation, although I have always taken the precaution of draining the wound down to the ureter with a rubber tube. This can be withdrawn by degrees after 48 hours if the wound remains clean. In my cases the wounds were all healed at the end of a fortnight, and I am advising this route for operation on the pelvic portion of the ureter because it is simple, easy, and rapid. It is not mentioned in those special books on this subject which I have had an opportunity of consulting, and I am convinced that it ought to be regarded as the most suitable route for a calculus impacted in the pelvic portion of the ureter.

Devonshire-place, W.

ROYAL SOCIETY OF MEDICINE.

ELECTRO-THERAPEUTICAL SECTION.

The late Dr. Lewis Jones.—The Standard Meal for X Ray Examinations.—Electrical Treatment of Stasis.—Glycosuria in Chronic Intestinal Stasis.—Simple Peptic Ulcer of Œsophagus treated by Ionisation.—Exhibition of Skiagrams.

A MEETING of this section was held on April 16th, Dr. IRONSIDE BRUCE, the President, being in the chair.

Dr. REGINALD MORTON alluded, in sympathetic terms, to the recent death of Dr. Lewis Jones, a loss which, he said, the section would not be able to make good, for Dr. Jones was truly the father of electro-therapeutics in the British Empire. The specialty began its upward trend when the deceased took charge of the electrical department of St. Bartholomew's Hospital in 1889—a fact largely attributable to his scientific methods, his thoroughness, and his accuracy. In the earlier days, when scorn was encountered, Dr. Jones never lost his good spirits or sought to retaliate, for he had a robust belief in its future, which had since been fully justified. He had suffered greatly from the loss of his son, who went down on H.M.S. *Hawke*, and that calamity he had never recovered from. Though a reticent man, Dr. Jones was very kindly, and one of the best features in his strenuous life was the encouragement he was always ready to give to younger aspirants in radiology. For himself (Dr. Morton) he had done many kindnesses, both scientific and in matters more mundane. It was, indeed, only those whose privilege it had been to know Dr. Jones intimately who could appreciate how great was the loss due to his death. Dr. Morton moved:—

> That this meeting wishes to express its deep sense of loss by the death of Dr. Lewis Jones, and its appreciation of all it owes to his work and personal influence, and desires to convey to Mrs. Lewis Jones an expression of its sympathy.

—Dr. E. P. CUMBERBATCH, in seconding the motion, said that he had only known Dr. Lewis Jones since 1911, but he soon discovered that he was a skilled physicist and an able physician. Ever since he had been associated with that gentleman he had found him a kindly light leading him through the gloom.—The motion was adopted by members rising in their places.

Dr. **REGINALD MORTON** read the report of the subcommittee of the section on a Standard Opaque Meal for Radiographic Examination of the Alimentary Canal. The subcommittee consisted of Dr. A. E. Barclay, Dr. A. F. Hertz, Dr. Reginald Morton, Dr. A. C. Jordan, and Mr. S. Gilbert Scott. Dr. Jordan did not subscribe to the main report, but submitted the separate report mentioned later. The report consisted of five heads: (1) The standard meal can consist of either bread-and-milk or porridge; (2) the total bulk of the meal should be about half a pint; (3) the meal should be mixed with two to three ounces of barium sulphate or bismuth oxychloride; (4) it should be taken when the stomach is as empty as possible; and (5) no aperient or other medicine should be taken within 36 hours of the first examination, and if the bowels are not opened naturally an enema should be given on the morning of the examination. Concerning the preparation of the bread-and milk, 2 oz. of white bread, devoid of crust, should be cut into small cubes; 8 oz. of ordinary or malted milk are boiled in a separate vessel with 2 oz. of bismuth oxychloride or barium sulphate; this is stirred and poured over the bread, sugar being added to taste. If porridge be chosen, 7 oz. of it are mixed with 2 oz. of bismuth oxychloride or barium sulphate and milk to bring the total to 10 oz., sugar to taste being added. The following useful notes were appended. Bismuth carbonate neutralises about 22 per cent. of the free acids of the stomach, but there is no evolvement of gas, as the carbon dioxide is dissolved as rapidly as it is produced (H. Finnemore and A. E. Barclay). The reduction of the acidity of the gastric contents tends to reduce the motor activity of the stomach and to interfere with the normal action of the pylorus. Bismuth oxychloride is slightly more opaque to X rays than is bismuth carbonate (Reginald Morton). Bismuth oxychloride is about one and a half times as opaque to the X rays as an equal bulk and twice as opaque as an equal weight of barium sulphate (Reginald Morton). Dr. Jordan's report stated that in his opinion the standard meal described was not suitable for the investigation of chronic intestinal stasis, and for this he recommended an emulsion containing 4 oz. of carbonate of bismuth with sugar of milk and water, two hours after an ordinary breakfast, without purge or enema.—Dr. **HERTZ** thought a note should be added to the effect that barium sulphate was a preferable salt for hospital purposes because, while the radiographic effect was equal to that of bismuth oxychloride, it was very much cheaper. Guy's Hospital had saved about £50 a year by the substitution.—Dr. J. **METCALFE** discussed the question of making the meal more palatable by the addition of substances like chocolate, especially considering that such people had some abnormality of the digestive apparatus, and a repugnant meal might modify the functional result.—Dr. **JORDAN** thought a difficulty in the matter of flavouring was that tastes differed so widely, and one would have to learn the personal predilection beforehand. With regard to his minority report, a person with intestinal stasis could more easily take an emulsion than a solid meal, and the emulsion would render opaque the food already in the stomach. Persons should come for their meal as hungry as possible.—The **PRESIDENT** expressed the hope that the members would all adopt the standard now submitted, especially as it would greatly help a reliable comparison of results. He supported the suggestion that a note should be added concerning the cheapness of barium sulphate.—Dr. **MORTON**, in reply, said it was intended to allow a free hand in regard to added flavouring; the aim should be to give a meal which should be as little objectionable as possible. He was in favour of adopting barium sulphate universally instead of bismuth oxychloride. This was agreed to.

Dr. F. **HERNAMAN-JOHNSON** drew attention to the Alternative Treatment of Stasis by Electrical Rhythmic Stimulation of Abdominal Muscles, such as by the sinusoidal current, rhythmically interrupted. This could be done in conjunction with a mechanical support and the use of cascara or paraffin for the first day or two.—Dr. **BARCLAY** expressed his agreement with Dr. Hernaman-Johnson's remarks.—Dr. **MORTON** also bore testimony to the value of the slow sinusoidal current, with about one alternation per second.—Dr. T. J. **BOKENHAM** expressed similar views.—Dr. **JORDAN** remarked that operation should only be done when other means had failed, and those who found other ways of dealing with intestinal stasis benefited not only patients but the profession.

Dr. **JORDAN** read a paper on Glycosuria in Chronic Intestinal Stasis. In the experimental methods of producing glycosuria three facts stood out prominently: (1) Claude Bernard's "diabetic puncture" of the floor of the fourth ventricle of the brain; (2) the administration of certain drugs, especially phloridzin; and (3) extirpation of the pancreas. The last of these threw by far the most light on the etiology and pathology of diabetes mellitus, though so far there was still no specific cure for the disease. But the knowledge of the relation of the pancreas to persistent glycosuria was leading to important pathological and therapeutic results. The pancreas was not at fault in every case of diabetes, though it was found to be diseased in 75 per cent. of the cases examined post mortem. Nor was pancreatic disease always accompanied by glycosuria. If all but one-fourth of the pancreas were extirpated there was no glycosuria. With regard to the pancreatic function in relation to chronic intestinal stasis the undue retention of intestinal contents in the lower coils of the ileum led to their invasion by microbes from the cæcum, and as these coils were almost sterile in health they could not deal with large doses of bacterial toxins, hence there was set up a general toxæmia. These overloaded coils constantly pulled upon the mesentery when the person was in the upright posture; a thickening might form at the point of greatest tension, the commencement of Lane's "ileal kink." Instead of that, however, in a feeble patient the mesentery yielded, and its attachment to the posterior surface of the abdomen slipped down, and a kink was produced at the duodenojejunal junction, and behind this kink the duodenum was distended. This and the exaggerated duodenal peristalsis were apparent with X rays. The congested duodenum was later invaded by bacteria, probably resulting in ulceration, or infection of the gall-bladder *viâ* the common bile-duct. One of the results of the succeeding general toxæmia was, in women, a mastitis of nodular form, which later proceeded to chronic cystic disease, and might eventually become cancerous. Chronic pancreatitis was another sequel; and both cleared up with the relief of the stasis. Most subjects of glycosuria suffered from chronic intestinal stasis. The urine contained indican, xanthin bases, and tyrosin; and one of the first indications in glycosuria was to relieve the chronic constipation. Transitory glycosuria was also often present in subjects of rheumatoid arthritis and in dyspeptics. Dr. Jordan concluded by mentioning cases in illustration of his thesis, and showed an instructive series of skiagrams.

Dr. **BARCLAY** described a case of Simple Peptic Ulcer of the Œsophagus and its Treatment by Ionisation.

Dr. **HERTZ** exhibited skiagrams illustrative of the following conditions: Achalasia of the Cardia, Syphilis of the Stomach, Appendicitis with Undescended Cæcum, Appendicitis with Colon situated entirely on the Left Side of the Abdomen, Heart pushed over to the Right Side of the Chest by Splenic Flexure, Hirschsprung's Disease in an Adult without Symptoms, tracings showing result of treatment of Atonic Dilatation of the Stomach, and tracings showing results of treatment in Severe Intestinal Stasis and Coloptosis.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A meeting of this society was held at the West London Hospital on April 9th, Dr. F. S. Palmer, past President, being in the chair.—Dr. Palmer showed: 1. A case of Progressive Muscular Atrophy, spinal type, in a male aged 39 years. 2. A case of Mongolism after eight years' treatment with thyroid extract and calcium salts, showing much improvement mentally and physically.—Mr. W. McAdam Eccles showed a case of a Bullet in the Heart Muscle, the patient being at the present time little the worse for its presence. It was demonstrated to the members present by Dr. Reginald Morton in the X ray department. The object was plainly seen, moving with the heart, just above the diaphragm and slightly to the right of the middle line. The patient was wounded on Nov. 4th last, the bullet striking him on the left shoulder. He walked a mile and a half to the hospital in Ypres, where first aid was given, and within less than 48 hours from the time he was wounded he was lying in St. Bartholomew's Hospital, his condition by that time being somewhat critical. The general opinion of the members was that the bullet was in the right heart close to the septum.—Dr. George Pernet showed a case of late Congenital Scrofulo-syphilide.—Dr. J. M. Bernstein showed a single woman, aged 26, who for four months had suffered from Spastic Paraplegia affecting both lower extremities.—Dr. Reginald Morton showed skiagrams of two cases of Œsophageal Pouch, two cases of Malignant Stricture of the Œsophagus, and a series of radiographs, taken at hourly intervals, from a case of Organic Hour-glass Stomach.—Mr. H. S. Souttar showed: 1. A case of Injury to the Circumflex Nerve resulting in Complete Paralysis of the Deltoid. Ultimately the distal end was anastomosed with the posterior cord of the brachial plexus. The muscle has recovered. 2. A child, aged 11 months, who had swallowed an open safety-pin 1 in. long, which had remained stationary in the duodenum for five days. It was removed by pushing the point through the wall and making a minute incision for the passage of the head.—Mr. O. L. Addison exhibited a case of Fracture of both Patellæ after 25 years. Skiagrams showed that the union was obviously fibrous and had been treated without operation. The patient suffered no inconvenience at the present time.—Dr. Arthur Saunders showed cases of Pulmonary Tuberculosis, and one case of Bilateral Thickening of the Tibial Periosteum.—Dr. Sydney A. Owen showed a case of (?) Toxæmic Jaundice with Hepatic and Splenic Enlargement.—Dr. Palmer, in opening the discussion, referred to the continued and regrettable illness of the President, Mr. Aslett Baldwin, and said there was every hope that he would be able to be present at the proposed reception on April 23rd. General support of all members and their friends was asked for, because after paying expenses the proceeds would be handed over for the benefit of the Belgian doctors and pharmacists whose country and homes had been devastated. Referring to Dr. Bernstein's case, he considered it one of disseminated sclerosis. He also referred to Mr. Addison's case of fracture of both patellæ.—Mr. McAdam Eccles made some interesting observations on the general question of fractures of the patella, including methods of treatment and some of the difficulties in the way of securing bony union.—Dr. Owen's case was discussed by Dr. Saunders.

ÆSCULAPIAN SOCIETY.—A meeting of this society was held at the Metropolitan Hospital on April 9th, Dr. David Ross, a past President, being in the chair.—Dr. Ross showed: 1. A man, aged 40 years, suffering from Ectopia Vesicæ. He was wearing a portable urinal and had found no difficulty in carrying on his occupation. 2. A man, aged 40, who complained of a woolly feeling of the calf, accompanied by swelling of the right knee. Diagnosis, arthritis due to septic mouth.—Mr. J. J. Udale showed a youth, aged 19 years, suffering from Parenchymatous Goitre, who had never resided out of London.—Dr. Sidney Foreacre showed a specimen of a Trachea and Œsophagus in which a new growth—epithelioma—occurred in the œsophagus at the junction of œsophagus with trachea. The growth infiltrated the trachea and thyroid gland, and pressure on the recurrent laryngeal nerves caused loss of voice. Tracheotomy was performed without avail.—Dr. Leslie Durno read notes of a case of Herpes following the distribution of the middle branch of the left fifth nerve—viz., the lower eyelid, cheek, anterior temporal region, side of nose, upper lip, half upper jaw, upper part of pharynx, left side of soft palate, and half of the uvula. Pain was present for ten days before the appearance of rash.—Mr. W. S. Soden showed a "Plaster-of-Paris" Kidney from a woman, aged 71, who was brought to the hospital dead, the cause of death being dissecting aneurysm of the descending aorta. The condition was probably tuberculous going on to total calcareous degeneration.—Mr. J. J. McNaboe showed: 1. A man, aged 38, suffering from Glosso-labio-laryngeal Paralysis with right hemiplegia of six years' standing. The overflow of saliva commenced three years ago. There was a double aortic murmur and the hemiplegia commenced suddenly. 2. A girl, aged 14 years, with psoriasis guttata on the knees and elbows and psoriasis punctata all over the body, back and front. She had improved since last seen 28 days ago, although not under treatment. 3. A woman, aged 32, with Graves's disease, accompanied by a visibly pulsating right lobe of thyroid. A question arose in this case whether the pulsation was in the thyroid or was conducted to it from a dilated arch of the aorta.

Reviews and Notices of Books.

An Introduction to the Study of Colour Vision.

By J. H. PARSONS, D.Sc. Lond., F.R.C.S. Eng. Cambridge: University Press. Pp. viii.–308. Price 12*s.* 6*d.* net.

THE vast literature of colour vision consists almost entirely of papers written in support of some particular theory. It is therefore with unusual pleasure that we welcome this excellent all-round résumé of the subject.

The book is divided into three parts: Part I., the chief facts of colour vision; Part II., the chief facts of colour blindness; and Part III., the chief theories of colour vision. The subject dealt with is so extensive that it is difficult to make a selection of those parts upon which comment would be of most interest. One of the most striking facts is described on p. 53, where we learn how similar the condition of dark adaptation is to colour blindness. When the eye has been kept in the dark for 20 minutes or so the condition of scotopia or twilight vision is induced, in which the sensibility of the retina for low degrees of illumination is enormously increased. Scotopic vision depends apparently "upon low stimulus values and a comparatively high degree of dark adaptation" (p. 57), and presumably these two processes are subserved by independent physiological mechanisms. When the scotopic eye is subjected to the various coloured lights of the spectrum, if they are of very low intensity, a greyish band is seen with its brightest part in the neighbourhood of the E line (530 $\mu\mu$), instead of near the D line (580 $\mu\mu$), as in the normal photopic eye. Now it is found that the luminosity curve of all colour-blind persons shows exactly the same characteristic. Further, the curve of values for bleaching visual purple is extraordinarily similar to the above curves, so that we are driven to regard the fact as of the greatest significance in any theory of colour vision. A warning may be given against a hasty conclusion from the statement that "accurate matches can be made between any two parts of the spectrum by merely modifying the intensity of one light." It is well known how difficult it is to compare the luminosity of two different coloured lights, as they give rise to quite different impressions. The statement quoted only refers to the scotopic eye, and gives no help in comparing two bright lights of different colours as seen by the normal or photopic eye; indeed, as we have seen, the appreciation of illumination is quite different in the two eyes. It is interesting to find that Mr. Parsons quotes evidence in support of the readings of the flicker photometer for lights of a different colour; they are, indeed, confirmed by Ives's results with the same instrument. He says that in the bright prismatic spectrum the red light (670 $\mu\mu$) appears about ten times as bright as the blue (480 $\mu\mu$). On the other hand, the achromatic scotopic value of the red is less than one-sixteenth that of the blue. Hence with failing light the reds appear almost black and the blues relatively bright. This is known as Purkinje's phenomenon, and clearly it depends upon the peculiarity of the scotopic eye.

Under the heading Recurrent Vision (pp. 85–100) are given accounts of the phenomenon of several images recurring at longer and longer intervals after the exposure of a scotopic eye to a momentary flash of light, and also of the sensations produced by intermittent flashes of light, flicker phenomena, &c. Porter's experiments on Talbot's law are given in considerable detail, but we have looked in vain for the observations of Stewart on the same subject.[1] In the next edition we should like to see some notice taken of Stewart's interesting curves, and a detailed account of the Benham's top phenomena. These are most important in their bearing on the tenability of any colour-vision hypothesis. In the present state of our knowledge no theory that has been advanced will account for all the facts of colour vision. The duplicity theory states that achromatic scotopic vision is carried out through the mediation of the rods alone, and that the perception of colour is dependent on the presence of the cones. It is well known that the rods are absent in the foveal area, and that in the peripheral parts of the retina rods become more abundant and cones fewer, just as the perception of colour diminishes towards the periphery of the field. Again, it has been shown that three whites of equal value to the normal eye, made by mixtures of red and blue-green, yellow and blue, green-yellow and violet, darken unequally with diminishing intensity. The photopic values of the mixtures are cone values, at lower intensities rod and cone values are mixed, and at the lowest only rod values persist. The Young-Helmholtz theory is the simplest way of accounting for the trichromatism of colour vision—i.e., that every known colour can be represented by a mixture of red, green, violet, and black sensations, as is well known by every one familiar with the three-colour process in art reproduction. Hering's theory postulates three pairs of primary colour sensations. This would explain nearly all the phenomena of after images and contrast effects, but it fails to give a reasonable explanation of the luminosity curves of the spectrum with the photopic and the scotopic eye; it is objectionable also in that it provides twice as many variables as the results of colour mixture demand.

We make no attempt to deal in a review with the seven other theories that the author describes. We can only refer our readers to this storehouse of information. The bibliography provided is excellent and has only a few trifling omissions, and throughout Mr. Parsons treats his subject with a scientific feeling that is admirable.

Lyon's Medical Jurisprudence for India, with Illustrative Cases.

By L. A. WADDELL, C.B., C.I.E., LL.D., M.B. Glasg., Lieutenant-Colonel, I.M.S. (Retired); Examiner in Medical Jurisprudence, Calcutta University. Fifth edition. Calcutta and Simla: Thacker, Spink, and Co. 1914. Pp. 867. Price 28*s*.

THIS work is offered as a complete exposition of the Indian medical jurisprudence of to-day, and the fact that a fifth edition has been called for shows that it has met with success. Not only is it a good manual on forensic medicine and toxicology in general, but it is rendered still more interesting by a description of the procedure in Indian law courts and of the peculiar circumstances under which the more common crimes come to be perpetrated in India and of the devices ordinarily taken to conceal crime in that country.

The detection of crime and the conviction of criminals in India are often rendered very difficult owing to special circumstances, such as the rapidity with which decomposition destroys dead bodies in the hot climate, and the facilities for concealing and destroying dead bodies, together with the general practice of rapid cremation or burial a few hours after death. Further, insufficient particulars of crime are of frequent occurrence in the police reports accompanying the alleged assaulted person or a decomposed dead body. Also, the untrustworthiness of native evidence is notorious. In nearly every case in law more or less false evidence is given, whether it be from fear, stupidity, apathy, malice, or innate deceit. The constant difficulty, therefore, is to sift the truth from the falsehood. A very common form of conspiracy is to cause a person to disappear and then to charge with murder some person against whom a spite is cherished. A plausible explanation is given of the disappearance of the body of the alleged murdered person, or a putrid corpse is obtained from the adjoining river, and after gashing it in several places it is brought forward as the remains of the missing individual. In such conspiracies circumstantial details are not infrequently sworn to by several persons, testifying as eye-witnesses to alleged facts of the murder, to the burial of the corpse, &c., so that conviction for the murder may be duly passed, and the falsity of the whole proceedings not be discovered until the reappearance alive of the person alleged to have been murdered. It has also to be remembered that a good deal of the crime against the person in India is the result of the primitive social state of the mass of the people and the observance of semi-barbarous cults and traditions handed down from the past, and often based upon primitive tribal instincts of self-preservation, but which now, under British rule, are illegal and criminal.

In this new edition the book has been thoroughly revised throughout and in great part rewritten to bring it fully up to date. An interesting new feature is the special chapter upon the Bio-chemical Test for Human Blood-stains, contributed by Lieutenant-Colonel W. D. Sutherland, of the Indian Medical Service. The process is described in its practical aspects. The great climatic difficulties hitherto experienced in carrying out this test successfully in India have now been effectively overcome. The vast number of illustrative cases which are quoted adds considerably to the interest of the work, and the extensive introduction of a new fount of clear heavy type for the headings and subheadings, and a fuller index, greatly facilitate reference. The text-book will be found useful not only by civil surgeons and medical students, but also by magistrates, police officers, and solicitors and barristers throughout India.

The Intervertebral Foramen: an Atlas and Histologic Description of an Intervertebral Foramen and its Adjacent Parts.

By HAROLD SWANBERG. With an Introductory Note by Professor HARRIS E. SANTEE. Illustrated by 16 full-page plates, none of which have ever before appeared in print. Chicago: Scientific Press. 1914. Pp. 101. Price $3.00.

Mr. Swanberg has taken a very limited subject for his study, and it stands to the credit of his ingenuity that he has managed to make a book out of it. The animal selected for his investigation is the "house cat"; but though we agree with the author as to its suitability from the point of view of size, we find it more difficult to approve of his further contention that "this animal and the human are very similar from a histologic and an anatomical standpoint."

---

[1] Proceedings of the Royal Society of Edinburgh, 1888.

It seems a pity that in making so concentrated an effort the author did not aim at better style of writing. In so small a compass there should be but little evidence of careless composition. Yet some passages detract seriously from the workmanship of the finished product—"How similar these bones are with those in the cat" and "There is a very small amount (of cartilage) on the articular processes, but considerable on the bodies," are examples. Throughout the book "ligamentum denticulata" and "ligamentum flava" are freely used. It may well be that this peculiarity of style has had its influence upon the opinion we have formed of the book; but we must own to the impression that, although a very small point has been studied, little has been made of it.

The Principles of Hygiene.

By D. H. Bergey, A.M., M.D., First Assistant, Laboratory of Hygiene, and Assistant Professor of Bacteriology, University of Pennsylvania. Illustrated. Fifth edition. London and Philadelphia: W. B. Saunders Company. 1914. Pp. 531. Price 13*s.* net.

A practical text-book that has reached its fifth edition has justified its existence and shown that it meets the requirements of a considerable body of students and practitioners of the subject to which it relates. In the present volume the whole sphere of hygiene, with its special departments connected with schools, the army, and the navy, is dealt with; and as the volume is handsomely printed in large type the 500 pages do not allow of much discussion in detail. It is accordingly, as its title indicates, an introduction to the study of the principles of the subject rather than a work to turn to for reference in practical difficulties.

The first chapters deal with air and ventilation; here it is said that expired air is "nearly always saturated with aqueous vapour": this should read, "always nearly saturated." The statement as to the effects of air vitiated by combustion is also obscure owing to careless punctuation. An unfortunate misprint on p. 73 in the formula for estimating the velocity of falling bodies, where $2\,gr$ is substituted for $2\,gs$, will perplex the student in a matter already somewhat difficult for the ordinary non-mathematical mind. Heating is next considered shortly in ten pages. The use of the term "indirect radiation" for what is generally known as convection in relation to systems of heating does not tend to clearness. Water and its supply and purification are next dealt with. The researches of McCarrison as to causation of goitre should have been referred to. A few pages only are given to sewage removal, and but little is said as to the construction of closets, soil pipes, and drains. It is rightly laid down that the soil pipe should be ventilated and disconnected from the drain, but the trap shown in Fig. 41 is an exceedingly bad one, and would undoubtedly lead to blockage in the drain. It has almost every fault that a trap can possess. Very little is said about the treatment of sewage, which is disappointing in view of the large amount of experimental work that has been carried out in the United States. Food, exercise, and clothing are then discussed briefly in Chapters VII. to IX.

Alcohol is considered by the author to be a food, but "the use of alcoholic beverages is to be condemned except under special conditions in disease where such a stimulant is required." Somewhat more attention might have been given to this subject. In dealing with clothing, the straw hat with broad brim is considered to be the most serviceable for inhibiting direct radiation of heat from the sun. No mention is made of the helmet, which (properly ventilated) is incomparably superior. The causation of disease is adequately dealt with, and full treatment is given to the subjects of disease prevention and disinfection in a very interesting book which forms a good general guide to a subject which has now become very far-reaching, and whose different branches require special study.

The Century of Columbus.

By James J. Walsh, M.D. New York: Catholic Summer School Press. 1914. Pp. 577. Price $3.50.

Dr. Walsh shares with many of us the opinion (or the fallacy, whichever it may be called) that "the old is better." This opinion is in itself old and was held up to reprobation by Tacitus through the mouth of his character, Marcus Aper, in the typically Tacitean sentence, "vitio autem malignitatis humanæ vetera semper in laude, presentia in fastidio esse." In a former volume Dr. Walsh held up the thirteenth century as the greatest of centuries, and it undoubtedly has high claims to this distinction; in the present volume he lauds another period, namely, 1450–1550, as being "among the greatest periods of human accomplishment in the world's history," and again we may say that he is right in the main. The Renaissance was a time when men were great in both good and evil. There were men like Colet, More, and Linacre, and men like Henry VIII., Thomas Cromwell, and Protector Somerset; there were Popes like Julius II. and like Alexander VI.; there were great artists who were good men like Michael Angelo, and great artists who were bad men like Cellini.

Dr. Walsh discourses pleasantly enough upon the Renaissance under three aspects, the Book of the Arts, the Book of the Deeds, and the Book of the Words. We learn that Raphael "by universal consent, was the greatest painter that ever lived," but that was a matter of opinion, and to-day opinion, while adjudging him the prince of decorators, would be found, upon intellectual grounds, to give pride of place elsewhere. Nor can we agree that Palestrina was, though undoubtedly the greatest musician of the period under review, "probably indeed the greatest of all times," although in his own line he is certainly incomparable. Again, on p. 434, Dr. Walsh, in speaking of the "De Imitatione Christi," says: "The Revd. Dr. Liddon, the great Greek lexicographer, called it 'the very choicest of devotional works ....'" This quotation may be from Liddell or Liddon, but the former was the Greek lexicographer, and not the latter. But whether we always agree with Dr. Walsh or not, he has given us a most interesting book, and the chapters on medicine and surgery are a useful résumé for the medical historian of the two arts during the period.

Town Planning, with Special Reference to the Birmingham Schemes.

By George Cadbury, jun. London: Longmans, Green, and Co. 1915. Pp. 201. Price 7*s.* 6*d.* net.

This very practical and useful book is of special interest to the medical profession as showing how intimately town planning is bound up with public health and social welfare. Mr. Cadbury appropriately quotes Charles Dickens as saying: "I have expressed again and again the conviction founded upon observation that the reform of the people's habitations must precede all other reforms, and that without it all other reforms must fail." The way in which all schemes of housing reform depend upon town planning is here clearly indicated, and the essential features of any town-planning scheme are said to be the following: (1) Limitation of the number of houses to the acre; (2) every house should be within reasonable distance of some open space; (3) careful planning of main roads, which should be wide enough to leave a separate track for tramways and should be connected up with a ring road, thus enabling heavy traffic to pass round the town instead of through it; (4) a belt of agricultural or park land should surround the town so as to prevent it sprawling out in the present formless, hideous fashion so characteristic of most growing English towns; (5) factory sites should be grouped together close to a railway siding, as this offers great advantages to manufacturers while preserving the amenities of the town; and (6) the whole scheme should be under the control of some responsible body which can treat the land as a whole and so harmonise conflicting interests.

These desiderata are, of course, rather in the nature of counsels of perfection, and can be obtained in their entirety only when a town is being built *de novo*, such as the Garden City at Letchworth. To this Mr. Cadbury very justly makes frequent reference; thus he points out that the death-rate there, with a population of 8000, partly residential and partly industrial, is only 6·1 per 1000. It is easy to exaggerate the effect of surroundings upon character, but Mr. Cadbury is in agreement with most social workers in supposing that the improved conditions of city life thus introduced will have an important effect in diminishing the amount of crime.

So far two schemes, both emanating from Birmingham, have received the sanction of the Local Government Board, and there are other schemes in preparation. These Birmingham schemes are described with great detail and with numerous excellent illustrations, and the particulars of one of them are given very fully in an appendix. Mr. Cadbury fully explains the various steps which have to be taken to conform with legislation by a local authority, and points out various reforms which would reduce the expense and simplify the method of inaugurating new schemes. He maintains that legislation for town-planning cannot be completely successful until the local authority itself owns the land. Some striking instances of the great expense involved in removing slum areas are given from Sheffield, Liverpool, and London.

Town planning takes into account the needs and possibilities of all classes of the community, and, as Mr. Cadbury well says, "it is not only the work of the architect and surveyor, but also of the business man, estate agent, and man of imagination." The book is well got up, with very good illustrations, and will be a most helpful guide not only to members of town councils, but to all who are interested in social reform.

LIBRARY TABLE.

Methods of Quantitative Organic Analysis. By P. C. R. KINGSCOTT, D.I.C., A.R.C.Sc., A.I.C., B.Sc. Lond., and R. S. G. KNIGHT, D.I.C., A.R.C.Sc., A.I.C., B.Sc. Lond. With diagrams. London: Longmans, Green, and Co. 1914. Pp. 283. Price 6*s.* 6*d.* net.—Quantitative organic analysis is admittedly more difficult of application than quantitative inorganic analysis, if only for one reason, that in the former case there are few ionic reactions, while in the latter they are the rule. Nevertheless, as these authors show, there are many schemes available for the quantitative analysis of organic compounds which give accurate results if pursued with care. The most useful section of this book, we think, is that on the analysis of organic compounds of technical importance, which include starches and sugars, indigo, oils, fats and waxes, alkaloids, alcohols, glycerine, phenol, acetone, chloral, and other definite bodies. The preceding chapters deal with ultimate analysis and the estimation of typical groups so commonly employed in research work and when theoretical considerations are in view. The book will prove a valuable help in the laboratory, where organic operations are not so widely followed, perhaps, as are similar inorganic operations, although the former are of quite equal importance. The instructions given are very clear, and indicate the joint authors' practical acquaintance with their subject.

English Medical Women. By A. H. BENNETT. London: Sir Isaac Pitman and Sons. 1915. Pp. 158. Price 3*s.* 6*d.* net.—Miss Bennett has written a pleasant and unpretentious little book about medical women, to which Mr. Stephen Paget contributes a kindly preface. There is nothing new in the book, but it will interest many of those who are not aware of the part played by women to-day in the profession of medicine. And medical women are by no means so novel as many people think. Besides those mentioned by Miss Bennett, we may mention the traditional medical work of Thecla in the primitive church, and in the eleventh century there were a number of medical women at Salerno, the mulieres Salernitanae, who were most successful practitioners. Miss Bennett describes with sympathy the struggles of Miss Garrett, as she then was, and of other pioneer women to obtain medical qualifications, beginning about the middle of the last century; this subject with other historical notes takes up the first part of the book. The second part is devoted to accounts of women's hospitals—i.e., hospitals worked by women, together with an account of the work being done at the seat of war by the Women's Hospital Corps. The next chapter gives an account, and a very thrilling one, of the work of the corps in Antwerp during the siege. Miss Bennett, a lay woman, has written a good book, but we would remind her that courtesy and kindliness to patients are not confined to hospitals worked by women, as she seems to imply on pp. 83 and 84.

The Report on Odontomes by the Committee appointed by the British Dental Association. With 94 illustrations. Published by the British Dental Association. Pp. 133. Price 6*s.*—At the annual meeting of the British Dental Association held in London in 1906 a collection of odontomes was exhibited, the specimens being lent by the various museums and private individuals. The scientific value of the collection was realised by the executive of the Association, and the preparation of an extended and illustrated account of the specimens was arranged for. The work was placed in the able hands of Mr. D. P. Gabell, Mr. W. W. James, and Mr. J. Lewin Payne, and they have the satisfaction of having produced the most valuable account of odontomes we are acquainted with. A careful search has been made for the records of cases of odontomes, and these have been collated and brought under different headings. This extended investigation has induced the editors to widen the scope of the term odontome, and they have included dental cysts, enamel nodules, and many specimens which resemble cases of gemination. A new classification has been suggested, the specimens being classed under three main headings—viz., epithelial, composite, and connective-tissue odontomes, each of these groups being again subdivided. An idea of the manner in which the subject is treated can be gleaned by taking as an example dentigerous cysts. First, there is a general account of the pathology and clinical features, then follows a summary of cases the records of which have been traced, 91 in number; this is followed by a full account, with illustrations, of the specimens shown at the meeting; and finally there is a bibliography. The editors have produced a work of considerable scientific value.

JOURNALS.

British Journal of Inebriety.—The April number contains an important article by Mr. F. S. D. Hogg, resident medical superintendent of the Dalrymple House Retreat, on the after-history and care of inebriates. Mr. Hogg bases his remarks in the records of a series of 1024 inebriate patients who have been discharged after varying periods of treatment at Rickmansworth. All the patients were men, and the majority belonged socially to the middle class. According to the histories obtained on admission, the patients were roughly divided into regular (or continuous) and periodic inebriates, the regulars outnumbering the periodics by about three to one. The writer's experience leads him to conclude that, while the duration of institutional care requisite to produce the best results varies with the circumstances of the individual case, there is an increased average of permanent effect corresponding to the increase in the duration of treatment up to about 12 months. The periodic inebriate appears to respond much better to treatment than does the regular drinker, 54 per cent. of the patients in the former category being reported as "doing well" after discharge, as against 37 per cent. of the continuous inebriates. The regular inebriates had on an average a longer period of excessive addiction before coming under treatment, but this fact does not appear to account for the less favourable results in their case, for in both regular and periodic drinkers the average duration of the inebriate habit was found to be practically the same among those doing well as among the total number of patients discharged. Mr. Hogg does not find that a hereditary history of inebriety, unless very pronounced and convergent, militates against the success of treatment. A hereditary history of insanity, on the contrary, affects prognosis very unfavourably. With regard to the influence of civil state, the married appear to have a three to two better chance of doing well than have the unmarried. Finally, Mr. Hogg notes that patients of phlegmatic temperament show the best results, while those of the highly nervous, and still more those of the passionate, type do least well.—An article by Mr. John Newton on Alcohol and the War gives further evidence from newspaper correspondents regarding the beneficial effect of the prohibition of the sale of vodka in Russia and of absinthe in France, and commends the example of the Allies to this country.—Dr. T. N. Kelynack contributes a short descriptive paper on the use of posters as a method of anti-alcohol propaganda during the present crisis. Some samples are reproduced in the article, and show a moderation of tone which is not invariable in temperance literature and which should greatly enhance the appeal of these posters to reasonable people.

Parasitology. Edited by G. H. F. NUTTALL and A. E. SHIPLEY, assisted by EDWARD HINDLE. Vol. VII., No. 4. March, 1915. Price 10*s.* net. Yearly subscription, £1 10*s.*—Warble Flies, a further contribution on the biology of Hypoderma lineatum and Hypoderma bovis, by Seymour Hadwen, comprises the results of experiments carried out in 1913 and 1914 on these interesting cattle parasites. The experiments, taken in conjunction with the evidence of Carpenter and Gläser, lend support to the view that after the larvæ of the warble flies hatch from the eggs, laid on the hairs of the cow, they bore their way directly through the skin and subsequently migrate to the gullet, where they get a freer supply of oxygen and a loose areolar tissue which offers comparatively little resistance. Later the larvæ migrate to beneath the skin of the back, where they produce the well-known warbles, and when mature escape from the cow by again boring through the skin.—A list of the trematode parasites of British marine fishes, by William Nicoll, will be extremely useful to all students of this class of parasites, as the author has given a list not only of all trematodes found in fishes caught in British waters, but also of those found in British fishes in other parts of the world, together with the authorities for each record.—Note on a Case of "Tick Paralysis" in Australia, by C. Strickland, records the symptoms of a boy of 11 years, who got a tick in his ear while in the bush in Australia. The boy suffered from paralysis affecting the face and legs, but recovered within ten days of the removal of the tick.—The Nuclear Changes in Agrippina bona Strickland, by C. Strickland, contains a criticism of certain statements made by Lewin regarding the author's original account of this gregarine.—A paper on a New Family and Five New Genera of Mallophaga, by Launcelot Harrison, comprises descriptions of five new species of this little-studied group of bird parasites. These five species are assigned to five new genera, named respectively, Eomenopon, Machærilæmus, Heteroproctus, Austrogoniodes, and Psittaconirmus. The paper is illustrated by two plates and three text figures.—Observations on the Biology of Ixodidæ, Part II., by George H. F. Nuttall, deals with the biology of 14 species of ticks. The author adds complete notes relating to the raising of five species from the egg to the adult—namely, Amblyomma hebræum, Dermacentor reticulatus, D. venustus, Rhipicephalus bursa, and R. sanguineus, all of which are important carriers of disease. Less complete accounts are given of the four species—Amblyomma variegatum, Hæmaphysalis cinnabarina, H. concinna, and H. inermis—whilst only short notes are given which bear on the two species Amblyomma splendidum and Hyalomma syriacum. The notes on Hyalomma ægyptium, Ixodes putus, and Rhipicephalus appendiculatus supplement those already published in Part I. Of special interest are the records relating to Dermacentor venustus, the carrier of Rocky Mountain spotted fever in Montana and the cause of tick paralysis in British Columbia.[1] This species is what is known as a three-host tick; the larvæ drop off their host after taking about three days for engorgement; the gorged larvæ moult and the unfed nymphs emerge and attack another host and feed for from 5 to 11 days; the gorged nymphs then drop off, and after an interval of from 14 to 15 days (at 24–30° C.) the adults emerge. These then attack a third host and copulation takes place on the body of the host, the male seeming to prefer the semi-gorged female. When the latter is fully gorged it drops off the host and after an interval of two or three days begins to lay eggs. 7140 fertile eggs were laid by one female observed by the writer. The life-cycle of this species may be completed in 68 days under the most favourable conditions, but in nature the time is said to be usually two years. According to the investigations of Rickett on Rocky Mountain spotted fever, this tick transmits the virus of the disease as a nymph if it has fed upon an infected host (man, monkey, guinea-pig, &c.) in the larval stage; when infected as a nymph the tick is infective as an adult, and larvæ, the progeny of an infected female tick, are also infective. With regard to Ixodes putus, the author describes the effects of the bite of a female which attached itself to his leg on July 13th, 1912. A well-marked and irritant swelling was produced and the area about the site of the bite remained discoloured till the spring of 1914. Even after this had disappeared the itching sensation continued to occur suddenly at intervals of about a month, the last date on which it returned being Jan. 20th, 1915. The persistence of the after-effects of tick bites is very remarkable and worthy of further investigation.—Artificial Parthenogenesis in Ticks, by George H. F. Nuttall, contains an extremely interesting note on parthenogenesis in Rhipicephalus bursa. When counting the eggs of this tick they are separated from the mass by immersing them in normal salt solution and rubbing them about gently with the aid of a camel-hair brush. The results show that the only unfertilised eggs that ever developed were those that had been subjected to this treatment, and the author is convinced that the parthenogenesis observed was artificially induced by the manipulation accompanying the enumeration of the eggs.

THE LANCET.

LONDON: SATURDAY, APRIL 24, 1915.

The Bacterial Infections of Projectile Wounds.

WE publish this week the third instalment of Sir Almroth Wright's Address on Wound Infections, which completes the pathological part of the remarkable dissertation which he delivered recently before the Royal Society of Medicine. The account of the new methods for studying the various factors in the treatment of wound infections will be read by all surgeons with extreme interest, and the far-reaching significance of that work will be at once appreciated. The note of challenge which is associated with all original scientific research is, of course, present, but not the most pedantic can find fault with Sir Almroth Wright's attitude towards the work and teaching of Lister. "The Listerian discovery," he says, "that prophylactic applications of antiseptics can, in the ordinary compound fractures of civil life, stave off wound infection has no direct application to projectile wounds. Prophylactic applications will give good results only when they can come into operation on the microbes. In ordinary compound fractures of civil life this will be the case. For here the microbes lie exposed on the external surface of the bone which has been thrust through the skin. The contrary holds for projectile wounds. For here the microbes are carried down deep into the tissues and lie on the internal surface of a torn and ragged track; and that track is blocked by blood clot and hernia of muscles." No one will dispute the deduction which follows upon this statement that prophylactic applications of antiseptics in such circumstances could only leave an incomplete sterilisation. And this being so, it becomes incumbent to find a procedure which will accomplish in the circumstances of projectile wounds what antiseptic solutions cannot, because of the inaccessibility of the infected parts and because, also, of the quenching of the antibacterial power of the antiseptics by the medium in which they have to be employed.

This week, too, we publish a memorandum by Sir Almroth Wright in collaboration with Mr. F. F. Burghard, Sir W. B. Leishman, and Sir Berkeley Moynihan, all employed with the Army Medical Service, and, like himself, with the rank of colonel. This memorandum should be read side by side with Sir Almroth Wright's address, which it may be said to a certain extent to translate from the language of the laboratory to the language of the hospital ward. The characteristics of projectile wounds and the bacteriology of the initial infection are described; the measures for checking the anaerobic infection of discharges and for preventing the development of tetanus, gas gangrene, and streptococcal infection are carefully considered; and the treatment is indicated where, by an unchecked anaerobic infection of the discharges, resistance of the tissues has been lowered and it becomes necessary to take immediate steps to stem microbic invasion. The general considerations in connexion with drainage and the measures for promoting the outflow of lymph from an incision or from the infiltrated wall of a projectile wound are put quite briefly. If the provision of an outlet by an incision is not free enough, even though assisted by gravity—and the memorandum suggests that in infected projectile wounds such measures for the relief of pent-up secretion will seldom be adequate—a hypertonic solution of salt is recommended to promote the outflow of lymph in order that the lymph already present, which has become poisonous to leucocytes and impotent upon bacteria, may be replaced by lymph favourable to phagocytic activity and inimical to microbes. Mr. H. Beckwith Whitehouse in this week's issue, in a note on the treatment of gunshot and shell wounds, makes special reference to carbolised glucose as a dressing. Lymph lavage can be promoted by inserting glucose and sodium citrate suppositories in the paths of wounds or along the tracks of bullets. This is one method of inducing an increased outflow of lymph from the wound; this outflow having a double action, in part it will mechanically carry away the microbes infecting the wound, but, further, this newly formed lymph has a far higher bactericidal action on the invading micro-organisms, and the phagocytes which it contains will also have a powerful action in destroying the bacteria present. Now that the principle is recognised that it is beneficial to assist the production of this increased outflow of lymph, we shall find many substances employed to stimulate it. The war will last long enough to give us much information as to the value of these various methods.

The particular indications for the employment of vaccine-therapy as part of the routine treatment of suppurating wounds are stated in the memorandum, the procedure being justified as likely to make it possible to employ conservative methods in a larger proportion of cases; while the frequent and efficient dressing of suppurating wounds with a mild aseptic is recommended. From every point of view the memorandum will be of great value to many of the medical officers now serving with the army. At present surgeons both at the front and at base hospitals are in a measure in doubt as to the best treatment to be adopted for the wounds which come under their care. The methods which have been recognised as of value in the treatment of the less intricate wounds of civil life have proved unavailing in dealing with wounds inflicted by rapidly moving bullets or by pieces of shrapnel, and infected with a virulent microbic flora. The investigations which have been undertaken under the ægis of the Army Medical Department will be of the utmost utility.

◆

The Final Report of the Royal Commission on Sewage Disposal.

THE issue last week of the final report of the Royal Commission on Sewage Disposal presents a general summary of conclusions and recommendations on a question which has been before the Commissioners for a period of 16 years. Since the Commission was appointed in May, 1898, nine reports have been issued, all of which, as they were published, have been dealt with from time to time in our columns. In the interim or first, second, fifth, and eighth reports the purification of domestic sewage discharging into streams received the attention of the Commissioners; the subject of the fourth and seventh reports was the discharge of sewage into tidal waters; while the third, sixth, and ninth reports related to the discharge of manufacturing effluents. The scope of the investigation has obviously been very wide, and as the sittings were continued fresh questions of a special nature were constantly appearing, inviting investigation with the view of suggesting solutions of particular problems which had arisen. The question, for example, of the discharge of sewage into tidal waters in relation to shell-fish pollution, brought to the notice of the Commissioners by the Local Government Board, involved a special inquiry into the number of serious outbreaks of enteric fever, ascribed to the eating of shell-fish obtained from sewage-polluted water. The recommendations subsequently made freed a considerable section of that industry from reproach. The closing of the sewage-polluted layings was amongst the preventive measures adopted and "oysters are in consequence far safer articles of diet than they were before the time of our inquiry," to quote the simple assertion of the final report. Quite recently the general recommendations for securing permanent and effective supervision and control both of sewage outfalls and shell-fish beds received the attention of the Local Government Board, which issued an Order under the Public Health (Regulations as to Food) Act, 1907, giving powers to local authorities to act in accordance with the Commissioners' recommendations.

In their sixth report again, which deals largely with the disposal of liquid wastes from manufacturing processes, the Commissioners recommend that standards of purification which call for no undue increase in the cost of production should be laid down, and that manufacturers should be required to comply with these standards. The Commissioners have considered each kind of trade waste separately, and, as there is a great difference between these wastes, they suggest what they consider a suitable standard for each. These suggested standards will, no doubt, be subjected to criticism by experts; indeed, some of them appear to have been arrived at on very slight evidence. But that is not a supremely important point, for the suggested limits of impurity are only intended as a guidance for a central authority when established. The larger local authorities, at any rate most of them, receive into their sewers trade waste of small volume without conditions, but many small authorities do not allow this, and there are circumstances in which such permission cannot be given as the manufacturers would be infringing riparian rights. Where it is feasible to get rid of trade waste through the sewers the problem is, of course, simplified, and in one of their earlier reports the Commission suggested the conditions under which this should be done, but, notwithstanding a general extension of the system under which purification of trade wastes is undertaken by local authorities, there will remain many cases in which manufacturers must be held responsible for the treatment of their own trade liquids, and it is with such cases as these that the first part of the ninth report deals. In a second part the Commissioners make some observations on the disposal of domestic refuse in rural areas where sewers are not available. In their opinion the water-carriage system is the best, where an abundant water-supply piped to the houses is available. Where, however, a water-carriage system is impossible dry closets may be used satisfactorily under proper supervision. This part of the report does not add very much to our knowledge, but it is interesting because it confirms that the tendency of modern sanitation towards the water-carriage system is a salutary one. In a minority report on the same subject Sir WILLIAM RAMSAY expresses views which are favourable to the extension of dry systems even when a water-supply is laid on in the houses, his reason being that the fruitful nitrogen of domestic sewage ought to be returned to the soil. The great waste of valuable material resulting from the discharge of sewage and slop water through drains is unfortunate, but it would be still more unfortunate if any discouragement of the present tendencies of sanitation should favour the spread of epidemic diseases.

The report contains an abundance of valuable material and represents an enormous amount of painstaking work contributed by recognised authorities on their subjects. It must be remembered, however, that some of this work will, sooner or later, be sure to be discounted in view of the steady and progressive march of scientific application to the problems of the disposal and utilisation of waste matters. The Commissioners' task has spread over 16 years, and the earlier recommendations may require modification, since it is probable that advances have already been made during the period in certain particulars. It is therefore reasonable to expect that the inquiry will have to be reopened sooner or later and the problems pursued through all their developments. It would, perhaps, be more satisfactory if the subject were taken up by a permanent department at the point where the Commission has now stopped; and, while the present is not the most suitable time to press for the appointment of a new bureau, there are good grounds for believing that the Government is not blind to the advantages which would be gained by the establishment of a department whose duties would be not only to deal with recent problems of sewage disposal but to ensure that full advantage is taken of the very valuable work accomplished in the past.

A Medical History of the War.

WITH a view to the compilation of an adequate medical history of the war a strong consultative body has been formed to consider the lines upon which such a history should be written. The work is intended to be upon a scale commensurate with the importance of the war, which means to say that no such medical history can ever have been contemplated, just as no such war has ever occurred. It will be presided over by the Director-General of the Army Medical Service, and the members have been well chosen in every department. Lieutenant-Colonel O. L. ROBINSON, R.A.M.C., and Sir WILLIAM OSLER, F.R.S., will be responsible for the subdivision of medicine; and Lieutenant-Colonel E. M. PILCHER, R.A.M.C., and Colonel F. F. BURGHARD for that of surgery. Colonel Sir WILLIAM LEISHMAN, F.R.S., and Captain F. W. ANDREWES, M.D., F.R.S., will supervise the subdivision of pathology and bacteriology; and Colonel W. H. HORROCKS and Lieutenant-Colonel W. W. O. BEVERIDGE that of hygiene and sanitation, this subdivision being left to military experts. The subdivision of statistics will be in the hands of Colonel H. P. W. BARROW, R.A.M.C., Dr. JOHN BROWNLEE, and Colonel W. N. BARRON, R.A.M.C.; while the historical subdivision and the secretarial work fall to the charge of Captain F. S. BRERETON, R.A.M.C., and Dr. W. MORLEY FLETCHER, F.R.S., the secretary of the Medical Research Committee under the National Insurance Act, a national body the resources of which have been placed at the disposal of the War Office.

We are sure that all our readers will welcome the information that it has been decided to compile an authoritative history of the medical side of the war. The lessons to be learned are so varied, and may be so valuable, that no pains should be spared by all concerned to make the work as full and accurate as possible. It is a fact that medical histories of past wars have been very disappointing, and no doubt this has been largely due to want of early organisation. And the start made by the new committee is, as a matter of fact, none too soon; for already some records have perished, and others would have similarly been lost if preparation for a sound official history had not caused those responsible for them to regard their trust in a more patriotic and scientific light. For the medical history of the war which is now projected is not designed to narrate only surgical and medical happenings with their statistical deductions. It is intended to give an account of the various experimental researches which are already being carried on in connexion with the maintenance of the health of the forces; and the value of these researches will be enhanced by the due preservation of all clinical records whereby standards of comparison can be instituted. We hope that the results of these various researches will see the light as soon as those concerned in their conduct feel that the conclusions will stand test, for guidance based upon sifted knowledge will be of the greatest service to our military medical officers in clinical treatment now, and perhaps for many a month to come.

Annotations.

"Ne quid nimis."

GOVERNMENT GRANTS FOR MEDICAL PURPOSES.

IN the current session of Parliament the Government will ask the House of Commons to vote £385,000 (compared with £480,000 last year) as the amount estimated to be required in the year ending March 31st, 1916, for the payment of grants towards the cost of the extension of sanatorium benefit to the dependents of insured persons under the National Insurance Act, 1911, and of the treatment of tuberculosis generally. Provision is included in this estimate for the statutory grants under Section 17 of the Act, and also for special grants towards the cost of schemes undertaken by the local authorities (or by combinations of local authorities), with the approval of the departments administering the grants, respecting the treatment of tuberculosis. The grants will be administered in England by the Local Government Board, in Wales by the Welsh Insurance Commission, and in Scotland and Ireland by the Local Government Boards for Scotland and Ireland respectively, and will be calculated on the basis of 50 per cent. of the net cost, as ascertained through the audit of their accounts, incurred upon the schemes by the Insurance Committees or local authorities, singly or in combination, after taking into account the sums applicable thereto out of funds under the National Insurance Act and other receipts in connexion with the schemes. The amount provided will be allocated between the three Local Government Boards and the Welsh Insurance Commission, and issues will be made from the vote to these departments by the Treasury from time to time as required. A vote of £25,000 will also be asked for to provide grants in the year ending March 31st, 1916, to assist in the provision of laboratory facilities with a view to the prevention, diagnosis, and treatment of disease. The money will be allocated, in accordance with a scheme made by the Treasury, to the English, Scottish, and Irish Local Government Boards, for the purpose of distribution by those departments, with the approval of the Treasury, as grants to county councils or sanitary authorities who are willing to provide or arrange for the provision of laboratory facilities with a view to the prevention, diagnosis, and treatment of disease. The scheme may provide that, if in any area the local authority is unwilling to arrange accordingly, a share of the grants can be allocated to the National Insurance Joint Committee for distribution to the Insurance Committee of that area towards the provision of such facilities and aids. The House of Commons will likewise be asked to vote £2015 for the expenses of the Highlands and Islands (Medical Service) Board for the year ending March 31, 1916, and £42,000 for a grant in aid of the Highlands and Islands Medical Service. The grant in aid will be paid to a separate fund to be called the Highlands and Islands (Medical Services) Fund. Subject to regulations to be made by the Treasury with respect to accounts, audit, and accumulation, the fund will be administered by the Highlands and Islands (Medical Service) Board in accordance with schemes to be approved by the Secretary for Scotland with the approval of the Treasury.

THE DANGERS OF SEA TRAVEL.

THE activity of German submarines and the measure of success attending their attacks upon defenceless merchant vessels have revived the question raised after the *Titanic* disaster as to the extent to which preparation for possible emergency is provided for on board passenger vessels. Would the instruction of passengers beforehand avail to diminish the loss of life inseparable from the sudden destruction of a large ship at sea? Correspondence in the *Times* and other newspapers tends to show that while some experienced travellers and sea-goers believe that more could be done, and ought to be done, by way of antecedent preparation for the worst, others with equal opportunity for forming a sound judgment are impressed with the difficulty of doing more than to give elementary directions to those who are not members of the crew; to allow the officers and crew to take the steps dictated by the circumstances when they have actually occurred appears to them the only practical course. In this matter it is as well to remember that the ships, whose danger is a cause of anxiety to all, may be divided roughly into two classes—those which make comparatively long voyages and those which should reach their destinations in the course of a few hours. In the case of the former, more is naturally possible in the nature of boat drill and instruction as to the routine to be observed than when the contemplated voyage is for a day or so only, or more likely for a night. The chairman of the Union Castle Line, whose views have been published in the *Times*, has pointed out that the nature of the emergency likely to call for the getting of passengers into boats varies at all times so greatly that it is almost impossible to give them any but the most elementary drill or instruction for the actual conditions that may occur. It may be possible, for example, to lower boats from one of the decks intended for the purpose and not from another, and it is of supreme importance that the operation of lowering boats should not be interfered with by the conduct of those to save whom they are intended. Sir Owen Philips is probably quite right when he contends that the boat deck should be free of passengers when the boats are being lowered away, and further when he indicates the saloon as a proper place for the assembling of passengers until preparations have been made for them to leave the ship. Here again, however, the variety of treatment accorded by the officers of German submarines to their victims compels us to see that there may be time on one occasion but not on others for disciplined measures, such as assembling in a given part of the ship, and that some parts of a ship may remain available when others, selected for the purpose beforehand, are not. With regard to life-jackets, there can be no doubt that these should be provided and accessible in sufficient numbers for the use of all, and that all should have some opportunity to learn how to put them on before the occasion to use them in earnest arises. Passengers, however, will differ from one another in their capacity to understand the not very complicated operation of putting on a life-jacket, and in home-coming ships from distant ports the opportunity for instruction will be greater than in others. At all events it can be given, subject to the observation that it is very undesirable to alarm needlessly the more timid travellers by ostentatious preparation for an event which may never occur. Fortunately for the task of life-saving at sea, which at any time may be thrust suddenly upon the officers and crews of our passenger-carrying marine, the circumstances of war must have eliminated from the passenger lists a large percentage of those who at ordinary times travel, and when danger arises are a helpless source of anxiety and responsibility to others. Assuredly this is above all a time at which those who would undertake voyages in order to gratify their curiosity or their love of change, their wish to seek a more congenial climate, or, in general terms, to travel unnecessarily, should be urged by their friends and by the dictates of their own good sense to stay where they are, or, at any rate, not to go down to the sea in ships. Those brave women and men who at the call of duty are daily risking their lives by sea travel are, many of them, on their way to scenes of more imminent danger than is afforded by the enemy's submarine tactics. These can be trusted to act in emergency with coolness and courage and to do their best for the safety of others as well as for themselves.

DR. RIBEMONT-DESSAIGNES ON PAINLESS LABOUR.

IN THE LANCET of August 1st, 1914, a summary was given of a communication to the French Academy of Medicine of the results obtained by Dr. Ribemont-Dessaignes at the Hôpital Beaujon by the administration in labour of a supposed new preparation of morphia, prepared by Paulin, obtained by subjecting the hydrochlorate to the action of fermenting beer-yeast. The result was practically painless labour, without muscular inhibition. In 113 cases there was no accident to the mothers, and though some of the 115 infants (there were two cases of twins) were at first sluggish at breathing, suspension by the feet or insufflation by the mouth was sufficient to determine their revival. Dr. Ribemont-Dessaignes made a further statement, in which he says: "In my publication of July I only had the clinical aspect in view. ...... The product supplied to me by Paulin appeared to me to have a different effect on parturient women to that of morphia *in the usual doses*, and seemed at first sight to be justly considered a new substance. ...... The experiments on animals which my colleague

Professor G. Pouchet undertook at my request led him to think that the treatment with fermenting beer-yeast had really modified the toxicity of the morphia, and made it more available for the accoucheur. But subsequent analyses made by several highly competent chemists seem to show that M. Paulin's product was simply hydrochlorate of morphia in solution, but *of the strength of 3·24 per cent.* instead of the usual 1 per cent. strength. Since September last I have only used in my clinique a solution of hydrochlorate of morphia pure and simple, of 3·24 per cent. strength, to which I add a little strychnine and caffeine. I inject 1 cubic centimetre [in the previous communication the injection is directed to be made under the skin of the abdomen]. If the result is not satisfactory I make a second similar injection at the expiration of two or three hours. The clinical results which I obtain are identical with those yielded by Paulin's solution. We are therefore justified in affirming that we may thus attenuate, or even suppress entirely in some women, the pains of parturition without danger to the mother (I have over 200 cases) and with no great risk to the child. The dose of morphia solution which at 1 per cent. arrests labour, at 3·24 per cent. does not; this is the point to bear in mind. It has long been known that the parturient woman tolerates opium well, and the present treatment exemplifies this tolerance. We have yet much to learn about morphia, and all this shows it. The desintoxication of morphia by Paulin's process has still to be proved." This statement by Dr. Ribemont-Dessaignes will be a disappointment to many who have published wild accounts of the procedure.

A SUGGESTION TO THE GOVERNMENT ON THE DRINK QUESTION.

THERE can be little doubt that the Government have got a difficult problem before them in regard to the drink question, but if all that is written is true and if the drinking of immature whisky is chiefly at the root of the mischief, why not stop its sale by enforcing at once a system of compulsory bonding? This would instantly check the sale of cheap whisky because it can only be cheap when it has not been matured. The maturation of whisky, in other words, costs money. In the final report of the Royal Commission on Whisky and other Potable Spirits issued in 1909 the following sentence occurs: "In our opinion, the compulsory bonding of spirits for a prescribed length of time could only be justified if it were established that such a restriction of trade is necessary *in the interests of public health.*" Surely the justification has arrived if it is true that the drinking of immature whisky has led to a serious inefficiency of labour. It is clearly only immature whisky that can be sold cheap. If, say, five years in bond were compelled the consumer would necessarily have to pay a higher price for the spirit, as there is loss by evaporation and there is the cost of storage. It will thus be appreciated that compulsory retention in bond would stop immature whisky drinking, and in many cases the drinking of whisky at all, since whisky would become automatically more expensive, and that without imposing a direct tax. At the same time compulsory bonding would remove the necessity for total prohibition, which would affect many classes quite unfairly. The suggestion that bonding for a period of years should be made compulsory is not impracticable, since in Canada the rule has held for a good many years that no whisky can be sold that has not been maturing in bond for not less than five years, and the regulation has worked to the advantage of the consumer.

POLYGLANDULAR SYNDROME, WITH TUMOURS IN THE SUPRARENAL AND PITUITARY GLANDS.

Dr. John Anderson, the director of the clinical laboratory of the Victoria Infirmary, Glasgow, has published in the March number of the *Glasgow Medical Journal* a case of some clinical and pathological interest, in which after death lesions were found in the pituitary and suprarenal glands. The patient was a woman aged 28 years, who for five years had suffered from indefinite and confusing symptoms, and in whom a development of certain secondary male sexual characters had taken place. Her illness began with vague general symptoms of asthenia and ovarian pain, coupled with irregular menstruation, which during the latter three years of her life passed into complete amenorrhœa. Her complexion changed from pale to red, her body gradually became stouter, and hair made its appearance on the face and body. At the same time a certain degree of proptosis became noticeable and she began to suffer from extreme headaches. On her admission to the Victoria Infirmary in 1913 the chief points to draw attention were well-marked exophthalmos, a florid complexion, and growth of hair in front of the ears and on the upper lip and chin. The patient looked older than her age. It was noted that the skin was harsh and dry and that there were petechial hæmorrhages on the arms and legs. No optic neuritis was found, though the headaches were very severe. While under observation the patient developed spontaneous petechial hæmorrhages on the slightest knock, even touching, so that she was never free from ecchymosis. Hæmorrhage from the bowel occurred several times. Death eventually took place by a gradual asthenia. At the post-mortem examination the thyroid was found to be slightly enlarged and congested. Microscopically it showed changes resembling those seen in cases after castration. Chronic interstitial nephritis was present, and the renal vessels were arteriosclerotic. The suprarenals were slightly enlarged, and in the medulla of the left was a small tumour, which, microscopically, was seen to resemble the structure of the zona fasciculata. The enlargement of the organ was due to an active hyperplasia. The internal organs of generation were senile in character. In the anterior lobe of the pituitary was a small adenomatous tumour. In the rest of the anterior lobe the chromophobe cells had markedly increased at the expense of the eosinophiles. The pars intermedia was abnormally cystic, while the posterior lobe was normal. Dr. Anderson's case resembles in many points one shown by Dr. H. G. Turney at the Royal Society of Medicine in 1913, and also one in Professor Harvey Cushing's book on the pituitary body (Case XLV.). In this instance there was pathological evidence of suprarenal hyperplasia and of both hyper- and hypo-functioning on the part of the anterior lobe of the pituitary. According to the author's view, the pituitary disturbance is the chief factor, and he regards the case as primarily one of hypopituitarism. The influence of the pituitary secretion on the ovary is stimulating in character, and its withdrawal leads to loss of sexual characteristics and atrophic changes. Its influence on the suprarenal and thyroid, on the other hand, may be regarded as inhibitory, and decrease of its function may allow of a hyper-functioning of these organs, with, in the case of the former, symptoms of hyperadrenalism and development of secondary male sexual characteristics. The association of changes in secondary sex characters and impairment of function of the suprarenal cortex is well established and has received considerable publicity. The term "suprarenal virility" has been applied in France to those female cases which as a result of suprarenal disease take on the secondary sex characters of the opposite sex.

THE PUBLIC HEALTH IN BRITISH COLUMBIA

IT is not unnatural that the public health report for British Columbia, which was recently noticed in our columns,[1] should be, as we said, exiguous, for the Province, with its enormous extent and its population of 400,000, has had no medical officer since February, 1914, when the late Dr. Fagan retired. Since that time the health work of the Province has been done by Dr. Bapty, formerly the bacteriologist, also in general practice, but since he has been on service as a major in the Canadian Mounted Rifles the office has been in charge of a sanitary inspector. A local correspondent tells us that this gentleman is a most competent courteous official, but scarcely able to deal with the problems brought for discussion by medical officers and sanitary engineers. There have been protests from the medical profession against this state of things, and the matter has been mentioned in the election campaign now proceeding, while the situation may entail increasing damage to health in the province. So progressive a colony as British Columbia should at once get herself out of the dark ages by putting the care of her public health in the hands of a medical officer. Dr. Bapty did good work by urgently pressing preventive inoculation against typhoid fever on the population even before the war.

THE EXTRACTION OF NEEDLES.

THE extraction of needles from tissues falls to the lot of every practitioner, and when access to the X rays is not possible, as frequently happens, the operation may be very difficult. In the *Inter-state Medical Journal* Dr. P. G. Skillern has published a paper on the extraction of needles without this aid containing many useful hints. For anæsthesia local infiltration with novocain-suprarenin solution usually suffices, but nitrous oxide may be used as well. In the hand the needle is usually driven in by the sewing machine, and since the eye is at the point goes eye foremost. Hence if a thread is carried in no attempt should be made to extract the needle by traction on the thread, not only for reasons that are obvious, but also because the thread forms a valuable guide to the position of the needle. In the foot the needle is also driven in eye foremost, since it is usually an ordinary sewing needle that has been stuck in the floor. The same holds for another common situation—the buttocks. The diagnosis is made by the history, the presence of a punctured wound, abiding pain, and especially by an area of circumscribed induration and tenderness at one spot. The last is important in locating the needle. Dr. Skillern's method of finding a needle without a skiagram depends upon the rigid observance of four rules: 1. The field must be absolutely bloodless. This is attained by exsanguinating the tissues from the fingers or toes to above the elbow or knee by a Martin's bandage. The first turns are uncoiled sufficiently to expose the field of operation; the remaining turns keep the blood back. 2. Follow the black track which leads from the skin puncture to the needle. The success of this step depends on that of the first. 3. Efficiently retract the tissues. 4. Lose no time in searching through the fat, since the needle travels directly to deep fascia or bone, the subcutaneous fat being too soft either to break or stop it. At the moment of impact the elastic fat is compressed and the needle is driven into and caught in a strong grip by the dense palmar or plantar fascia or by bone. When the pressure is released the elastic fat springs back into place and, as it were, swallows up the needle. With the patient properly anæsthetised a free incision is made directly down to the deep fascia. Its length varies directly with the depth of the subcutaneous fat. In some cases time is gained by adding another limb so as to make a T-incision, or even a crucial incision may be necessary. The incision includes the skin puncture and the black track is exposed and followed to the deep fascia. The latter is thoroughly exposed by retracting the flaps. The needle is usually found sticking into the deep fascia. If it has penetrated more deeply this fascia must be incised and retracted. The underlying muscles or tendons are examined each in its own plane. This method of "plane dissection" is very important. If the needle is not in one plane it must be in some other, and each plane must be successively explored. Before each plane is dissected it is palpated with the tip of the little finger or explored with the handle of the knife, which may scrape against the needle. The bones form the last plane, and when they are reached the needle has probably been found. It should be carefully extracted in its own axis, for it is liable to break. By this plan the usual causes of failure—too small an incision and insufficient retraction—are eliminated, and, contrary to prevailing opinion, a skiagram is not always essential.

THE LATE DR. A. A. W. HUBRECHT.

THE death of Dr. Hubrecht has removed a very considerable person from the zoological world. Among those who have devoted themselves entirely to the purely zoological side of biology—not being concerned, that is, with the more theoretical aspects of that science, heredity, sex, and so forth—Hubrecht has occupied for some years a prominent position. His researches have been mainly along two lines. The best-known work, perhaps because it took up many more years in its execution, dealt with the group of worms usually called nemertina. A reference to any zoological text-book or treatise will at once show the large number of important contributions which this zoologist has made to our understanding of those animals. The genus Hubrechtia remains as a sign of his acknowledged mastery of this group. In more recent years Dr. Hubrecht devoted a great deal of attention to the development of the mammalia; while besides these two main lines of work he contributed memoirs on various biological topics. Dr. Hubrecht was particularly well known in this country by reason of his frequent visits to the British Association and his thorough acquaintance with English. He contributed many of his memoirs to the *Quarterly Journal of Microscopical Science*, and wrote for the magnificent series of "Reports" obtained by the voyage of H.M.S. *Challenger* the part dealing with the Nemertina.

[1] THE LANCET, March 6th, 1915, p. 505.

THE TREATMENT OF SCIATICA.

Two papers of some interest, one on the treatment of sciatica by perineural infiltration with saline, by Dr. William M. Leszynsky, and the other on its treatment by epidural injection of saline, by Dr. Israel Strauss, appear in the *Medical Record* (New York) of Feb. 6th. The perineural infiltration method was first brought prominently to the attention of the medical profession in 1907 by Dr. J. Lange, of Leipsic. It consists in the injection of a large quantity of fluid under pressure directly over the sciatic nerve. Prior to that date injections of sterilised air, similar in principle, had been given with conspicuous success in cases of sciatica, lumbago, &c., in France and elsewhere. For a long time previously, too, injections of cocaine and analogous medicaments had been used in sciatica with good results. The idea of the injection of air, or of fluid in quantity, is that thereby adhesions in the neighbourhood of the nerve are loosened or stretched or broken down. Dr. Leszynsky is of the opinion that, since prompt relief can be obtained in acute and recent cases, where the formation of adhesions can scarcely have taken place, the relief of pain must be due either to blocking of sensory conductivity or to the pressure and absorption of the fluid producing changes in the circulation and nutrition of perineural structures. The technique of the method is simple enough. With the patient lying on his face with legs extended, and a firm pillow under the lower part of the abdomen, the point of exit of the great sciatic from the pelvis is determined in one or other of the usual ways, the skin is painted with iodine, and then the needle of a syringe is pushed in perpendicularly till the sciatic sheath is reached, when the patient will experience a sharp pain radiating down the thigh, or in the heel, or there may be a twitch of the leg or calf. Sterile warm (95° to 100°F.) physiological saline solution is then injected by the syringe, in quantity ranging from 80 to 120 c.c. There may be aching or heaviness or numbness in the limb afterwards, but this rapidly passes off. The interval following the first injection, before another is given, naturally varies according to the degree of relief obtained. Sometimes only one injection is necessary. Dr. Leszynsky is in the habit of waiting from 36 hours to one week before repeating the injection. It is most important to note that it is not intended that the nerve sheath should be entered by the needle, otherwise the forcing of a large quantity of fluid into the nerve trunk may result in a traumatic neuritis. It is recommended that a blunt stylet, projecting 1 millimetre beyond the cutting point of the needle, should be inserted when the latter is once through the skin, to obviate puncturing a blood vessel or the nerve sheath. Dr. Leszynsky does not advise this perineural treatment in every case, but mainly for subacute and chronic intractable cases, and he has used it with success some 160 times. As for the epidural method, Dr. Cathelin, of Paris, recommended it originally, and employed it in various conditions with uniformly good results. For the purposes of epidural injections the epidural space begins at the first sacral vertebra, where the dura mater ends, and it extends down to the sacrococcygeal articulation, where the injections are made. The opening into it is bordered laterally by two prominences, the cristæ sacrales laterales, which are usually easily felt by the finger, and it is covered by the dense ligamentum sacrococcygeum. It lies generally about two centimetres above the end of the gluteal fold. Dr. Strauss has his patient lying on the side, with knees and thighs flexed. After anæsthetising the skin over the foramen with novocaine he pushes through the ligament and into the foramen a strong needle, 1 mm. in calibre, for a distance of about 6 cm., to reach the second sacral vertebra. The injection consists of warm saline. To the first 10 or 20 c.c. of saline is added 0·3 c.c. of novocaine with adrenalin and a few minutes allowed to elapse. Then some 60 or 80 c.c. in all are injected. As a rule the patient feels merely an uncomfortable pressure in his lower spine. In some 19 cases Dr. Strauss has obtained excellent results. He also recommends it mainly in subacute and chronic cases, and holds that it is preferable to perineural infiltration, inasmuch as no injury to the nerves has been reported following on epidural injection. He considers that many cases of sciatica are really due to a root neuritis, a "radiculitis" of the roots of the nerve, and these are the cases more particularly where epidural injections are indicated.

A NEW METHOD OF DIFFERENTIATING BETWEEN EXUDATES AND TRANSUDATES.

HITHERTO the method most usually adopted to distinguish between these two classes of fluids has been that of Rivalta. This observer showed that if a drop of a transudate, which is of a lower specific gravity and contains less cellular elements and less albumin than an exudate, be added to a 2 per cent. solution of glacial acetic acid, the fluid remains clear, but if an exudate be added a bluish trail like a puff of cigarette smoke is seen as the material makes its way down through the fluid. In the last number of *Annali dell' Istituto Maragliano* Dr. F. Morelli describes a new method which seems to yield much more certain results when compared with those obtained by using Rivalta's reaction on the same fluids. This new method is based on the reactions between mercury and different forms of albumin, causing precipitates and forming corresponding metallic albuminates. Dr. Morelli noticed that when drops of fluid obtained from a serous cavity were let fall on a saturated aqueous solution of corrosive sublimate the characteristics of an exudate were shown by the formation on the surface of the solution of a dense, compact coagulum of albumin, yellowish in colour, often remaining adherent and suspended, but sometimes falling in a mass without disintegrating. When, on the other hand, the fluid was of the nature of a transudate a coagulum of albumin formed on the surface which very quickly split up into small particles and fell to the bottom. The only exception to this rule was in the case of pleuritic exudates of a tuberculous nature in which the reaction was always negative, and this uniformly negative reaction furnishes an important indication in etiological diagnosis. Rivalta's reaction did not show this difference

CHINA MEDICAL MISSIONARY ASSOCIATION.

THE biennial conference of the China Medical Missionary Association was held on Feb. 2nd at Shanghai, with Mr. Duncan Main as president, when a discussion was opened on Preventive Medicine in China by Dr. Arthur Stanley, health officer of Shanghai. Dr. Stanley's paper was entitled "How to Initiate Public Health Work in Chinese Cities," and was much to the point. Essentials in Dr. Stanley's opinion are: some form of authority for control of finance, staff appointments, and general policy, such as a municipal council; secondly, a highly trained health officer; thirdly, sanitary law; fourthly, money, which would be mainly obtained from the sale of ordure, house refuse, together with market, slaughter-house, and licence fees. A fifth necessity was a well-appointed central office, including a sanitation laboratory and a staff, which in the near future should be wholly Chinese. Dr. Stanley concluded: "The practical prevention of disease is now reduced to simple terms and scientific precision. The main thing in China would appear to be to prevent waste of effort and to direct energy into the right channels on those measures which mean most." That sanitary work is needed in China is obvious from an excellent paper read by Dr. Wu Lien Teh—well known to many friends in England, made during his Cambridge days and since, as Dr. G. L. Tuck—the Director of the Army Medical College at Tien-tsin, who pointed out that though enteric fever, pneumonia, and most diseases due to alcohol are much rarer in China than in Western lands, yet many preventable diseases, such as small-pox, typhus fever, plague, and leprosy, together with many skin affections, were far too common. Dr. Wu recommended the teaching of elementary hygiene in the schools, the establishment of sanitary boards and social leagues, the members of which should look after district nursing and the distribution of wholesome food, especially milk, and should carry on an educational campaign. Also there should be established at Peking a central public health institute. By these means he hoped that a great and necessary work would be done—namely, the awakening of a sanitary conscience in China. Among other papers we may mention the following. Obstetrical Experience in Futsing City, by Dr. Mabel C. Poulter, who gave an appalling account of native methods in vogue, and showed the very good results from the treatment in hospital. Out of 1291 cases there were 8 maternal deaths, and of these 3 were emergency cases who had been two or more days in labour and had been attended by native midwives. Dr. Logan, of Changteh, communicated his five years' experience in aseptic surgery at an inland hospital. Of clean cases—i.e., those in which the surgeon could exercise control before, during, and after operation, 97·5 per cent. healed by primary union. Altogether the conference was a great success.

MEDICAL MEN AND THE LAY PRESS.

WE are at all times of opinion that medical men writing upon medical subjects in the lay press should exercise great care and discretion in their choice of subjects and in their manner of approaching them. Advice given in popular terms which will tend to the preservation of the public health can be very useful, and information as to the nature of a particular disease if it will have the effect of sending patients in the early stages to seek medical advice—general medical advice, that is, and not advice from Dr. A or Mr. B—may not be amiss in some instances. Nevertheless, to give a bird's-eye view of some form of disease, which shall afford the requisite amount of information without raising doubtful questions, causing needless alarm and anxiety, or leading laymen to think that they know all about the subject discussed, is far from easy, and the attempt to do so should generally be avoided. In any case, the topic selected should be treated cautiously and, above all, seriously, efforts to attract by "bright" pen-pictures, by epigram, or by irony being avoided as sure to be misunderstood. Recently a writer, described as a physician, discussed "kidney disease" in the *Sunday Chronicle*, and was betrayed, we imagine, by his desire to captivate the attention of his readers, into writing a great deal which, for the reasons suggested above, he had better have left alone. Towards the end of his article the following passages occur. We quote them in the form in which they appear in the pages of the *Agents' Journal and Official Gazette*, where they are accompanied by the expression of strong and not undeserved disapproval.

> There is no treatment for Bright's disease, and no drug has the least effect on it. ...... My own advice is, I fear, somewhat unscrupulous. It is to effect as big and as many life policies as you can before you are discovered (*sic*) and then go and follow an Arcadian existence in the South Sea Islands ...... and do your relatives a good turn in the end.

On the face of it this constitutes an invitation or recommendation to attempt a fraud, and a signed article in the *Agents' Journal* so treats it, stigmatising the whole passage as "a slander against, and an insult to, the medical profession," and hoping that "those organs which may be regarded as entitled to speak for the medical profession will, without delay, repudiate and discountenance 'advice' so discreditable and wicked as that we have quoted above." So far as we are concerned, we most willingly repudiate any such advice, and are fully prepared to "discountenance," not only the passages selected for condemnation, but the whole article in which they occur as being entirely unwise and undesirable. We do not think the writer intended to advise the commission of a fraud or even to suggest that its perpetration would be easy. In an earlier part of his article he informs his readers that disease of the kidneys is frequently first discovered when the patient tries to insure his life, not having before been suspected, so that he would be no doubt the first to point out the impracticability of following his own recommendation. We fear that he meant to be "bright" or "smart," and disease is best not treated in that literary manner.

WE regret to report the death of Sir Thomas Clouston, which occurred at Edinburgh on April 19th, within a few days of the attainment of his seventy-fifth year.

Dr. James Alexander Murray has been appointed by the executive committee general superintendent of the Imperial Cancer Research Fund and director of the laboratories.

THE work of the Departmental Committee appointed in March, 1914, to inquire into and report on matters affecting the care of the blind was interrupted by the outbreak of the war, but it is hoped that the sittings will be resumed during this year.

MEMORANDUM ON THE TREATMENT OF THE BACTERIAL INFECTIONS OF PROJECTILE WOUNDS.

BY

COLS. F. F. BURGHARD, SIR W. B. LEISHMAN, F.R.S.,
SIR B. MOYNIHAN, AND SIR A. E. WRIGHT, F.R.S.,
ARMY MEDICAL SERVICE.

IT is proposed in this Memorandum (*a*) to synopsise the experience obtained in connexion with wounds in this war; (*b*) to supplement this by setting out the chief data which have been furnished by a bacteriological study of the wounds; and (*c*) to lay down certain broad principles of treatment for the guidance of those who have not seen the conditions in the present war, or who have seen only an early or a late phase in the history of the wounds.

The present Memorandum will be followed up, as soon as certain researches are completed, by Memoranda on the Employment of Antiseptics and Vaccines respectively.

I.—CHARACTERS OF PROJECTILE WOUNDS AND BACTERIOLOGY OF THE INITIAL INFECTION.

The wounds made by projectiles are not in any respect comparable to clean-cut, swabbed-out, aseptic operation wounds or to any of the accident wounds seen in civil surgery.

Where the projectile has passed through the flesh there will, in the ordinary case, be a torn and ragged track, with an irregular surface of heights and hollows produced by the hernia of muscle and the retraction of the severed fibres. Where the projectile has come against bone this will be generally splintered, and the track will lead down into widely ramifying crevices between comminuted fragments.

There will also in practically every artillery wound be included foreign matter—a projectile, or shreds of clothing, or fragments of bone, and with these lacerated muscular and connective tissues which will slough. In addition, the wound will be full of blood clot and effused lymph. And lastly, the projectile, when it has traversed soiled clothes or a soiled skin surface, will have carried in microbes, and these will have been sown all along the track.

This deep sowing of microbes, taken together with the blockage of the wound by blood clot, and the not infrequent obliteration of a section of the track by hernia of muscle, will, in the case of any deep or perforating wound, make the effective sterilisation of the wound by antiseptics impossible.

Of the microbes which are carried into the wound the most formidable are the anaerobes and facultative anaerobes. These are found in very large numbers in practically every case arriving at the base from the front.

Three species of microbes here come into consideration. The *streptococcus*, the one microbe which is, one may say, invariably present, is primarily responsible for the suppuration which will supervene in the wound. The *tetanus bacillus*, or a bacillus which is morphologically indistinguishable from this, is present in the pus from a certain proportion of cases. And in practically all the wounds we have also the *bacillus aerogenes capsulatus* of Welch (*bacillus perfringens*). This produces a characteristically offensive, thick, frothy, rusty brown, sometimes almost fæcal, discharge.[*]

The anaerobic infections of the imprisoned discharges which are here in question, may, if unchecked, lead to graver consequences. The streptococcal infection may lead to an infection of the tissues in the form of erysipelas or deep cellulitis, and it may culminate in septicæmia. The tetanus infection will, if the microbe cultivates itself sufficiently freely and elaborates enough toxin in the wound, give rise to tetanus. And the bacillus of Welch, when it manages to invade the tissues, will generate gas, producing a gas phlegmon and also an obstructive gangrene in the affected limb (so-called *gaseous gangrene*).

II.—MEASURES FOR CHECKING THE ANAEROBIC INFECTION OF DISCHARGES AND PREVENTING THE DEVELOPMENT OF TETANUS, GAS PHLEGMON WITH GANGRENE, AND STREPTOCOCCAL INFECTION OF THE TISSUES.

The rational line of treatment for the prevention of the grave sequelæ which are here in question will be to check at the earliest possible moment the anaerobic infection of the discharges.

The wound ought to be freely opened up. It ought then to be carefully cleansed with an antiseptic solution (*vide* Memorandum on Antiseptics—Therapeutic Employment); all foreign bodies, sloughs, and blood clot (as far as this is possible without risk of hæmorrhage) being carefully removed. Then a very wide drainage-tube which will admit air to the interior ought to be inserted, and, especially in those cases where there is much laceration, steps ought to be taken to promote the outflow of lymph from the walls of the wound (*vide infra* Section IV.).

By such steps we may hope to put an end to the anaerobic infection and to obtain instead of foul smelling, gas impregnated, decomposing discharges a more or less "laudable pus."

Where owing to the exigencies of war conditions it is for the moment impossible to carry out the required surgical measures or where from the nature of the case the wound cannot be effectively drained, it will be specially important to abstain from doing anything which might still further favour the anaerobic infection.

(*a*) Wounds should not be sewn up after operation. We can never be sure that the projectile has not carried in infection, and we cannot under war conditions and during transport count upon the patient being kept, as he should be, under continuous observation. Plugs, except where there is actual risk of hæmorrhage, should never be left behind in the wound, for they bank back the discharges and establish anaerobic conditions. For the same reasons it will be necessary to see that the wound is not wrapped up air-tight, that discharges are not allowed to dry upon the bandages, and that the mouths of drainage-tubes are not blocked by the pressure of the dressings.

(*b*) Moreover, it will, pending the opening up and cleansing of the wound, be very desirable to take certain specific prophylactic measures. By an injection of antitetanic serum we may hope to neutralise any tetanic poison which may be absorbed from the wound.

(*c*) Further, by the injection of a prophylactic dose of a vaccine containing the bacillus of Welch and the streptococcus (issued as *Combined Antigangrene and Antisepsis Vaccine*) we may hope to stave off an invasion of the tissues by these micro-organisms (*vide* Memorandum on the Employment of Vaccines).

---

[*] *Probable derivation of these anaerobic microbes.*—All these microbes would seem to be of fæcal derivation. The bacillus perfringens in particular is an inhabitant of the alimentary tract, and it can (by implanting in boiling milk and anaerobic cultivation) be readily recovered from the fæces of men and animals, from earth soiled with fæces, and from the soiled uniform of the soldier.

It must, however, be clearly realised with regard to these measures that they are only temporising methods, and ancillary to such cleansing and drainage of the wounds as may in a particular case have been for the moment practicable.

III.—TREATMENT OF STREPTOCOCCUS INFECTIONS OF THE TISSUES AND GAS PHLEGMON.

When by an unchecked anaerobic infection of the discharges the resistance of the tissues has been lowered, and these have been invaded by microbes, it will be necessary to take immediate steps to stem that invasion.

We have at disposal two different methods of procedure: (*a*) We may take steps to increase the antibacterial powers of the blood fluids; and (*b*) we may lay open and effectively drain the tissues (*vide infra* Section IV.) and so bring back to these their normal resisting power. These methods will be applicable according to circumstances, separately or in combination.

A streptococcal infection which takes the form of erysipelas can practically be always promptly extinguished by an injection of streptococcus vaccine (*vide* Memorandum on Employment of Vaccines) without recourse to any surgical measures.

When a streptococcal infection takes the form of a diffuse cellulitis vaccine therapy will rank only as an auxiliary measure, and the laying open of the infected tissues and the establishment of effective lymph lavage by the method indicated in the next section will be the essential.

What applies to the case of streptococcal cellulitis applies *a fortiori* to all infections of the tissues by the *bacillus of Welch*. In every case these must be opened up and effective lymph lavage induced.

In connexion with the actual surgical measures we have two cases to consider:—

(*a*) Where the infection follows a superficial course manifesting itself in dusky blotchings of the skin and gaseous emphysema in the subcutaneous tissue, it will suffice to open this up freely by incisions carried down to the plane of the muscle. (And it is here thrown out as a suggestion that a more efficient evacuation of the lymph would be obtained if the incisions were disposed transversely instead of axially to the limb.)

(*b*) Where the deeper tissues are diffusely invaded, and where the limb, owing to the internal tension, has assumed a blanched, wax-like appearance, incisions into the subcutaneous tissue would not relieve matters, for the underlying muscle would protrude into and block the wounds. In these eminently dangerous cases it will generally be necessary to amputate. But it may sometimes be possible to save the limb by the free opening up of the deeper tissues and the introduction of large drainage-tubes.

In amputating for diffuse infection of the deeper tissues, or, as the case may be, for a progressive infection of the subcutaneous tissue, it is advisable, inasmuch as it is in these cases essential to obtain an absolute maximum of drainage, to do the flapless amputation—i.e., to cut across all the tissues at one and the same level and to leave the wound completely open.

IV.—GENERAL CONSIDERATIONS IN CONNEXION WITH DRAINAGE AND MEASURES FOR PROMOTING THE OUTFLOW OF LYMPH FROM AN INCISION OR THE INFILTRATED WALL OF A WOUND.

The primary object of all opening up of wounds and infected tissues, in short, of all drainage operations, is, of course, to provide issue for pus and infected discharges.

But the mere provision of an outlet is not enough, nor is it enough to see the outlet so disposed as to allow of gravity carrying off accumulated discharges.

What we are seeking to secure will not have been attained until such lymph as may have become poisonous to leucocytes and impotent upon bacteria has been extracted from the tissues; until that lymph has been replaced by a lymph which is favourable to phagocytic activity and inimical to microbes; and until this last is being "drawn" into the wound and is establishing in it conditions which are favourable to healing.

When anything less than this has been achieved by the use of the knife and, in particular, in the case where in despite of incisions the infective process has advanced, our drainage operation will have failed in its object, and our failure will be attributable to a sealing up of the fenestræ in the tissues and a stanching of the lymph outflow.

The remedy for this is to apply to the wound a hypertonic solution of salt to promote the outflow of lymph.

For ordinary use the best application will be a 5 per cent. solution of common salt combined with ½ per cent. citrate of soda to render the lymph incoagulable. Where citrate of soda, or a similar decalcifiant, is not available a simple 5 per cent. solution of salt will serve. Sea water, this being equivalent to a 2·5 per cent. solution of salt, may also be employed. In dealing with dry and infiltrated wound surfaces stronger solutions of salt (up to 10 per cent.) will be found to resolve the induration and to clean up the wound surfaces much more quickly than weaker solutions.

In the case of deep wounds the simplest procedure will be to pour in the hypertonic solution and then plug lightly with gauze. Superficial wounds may be dealt with by laying on gauze thoroughly soaked in the solution. The limb should then be wrapped in waterproof material to prevent the bed becoming soaked with the very copious discharge, and an application of vaseline will prevent irritation of the skin and stinging on freshly cut skin surfaces.

The "drawing agent" has done its work as soon as it has checked the spreading invasion of the tissues or has cleaned up the dry and indurated wound surface, and this last has clothed itself in bright coral red granulations. The hypertonic salt solution may then be replaced by some simple dressing (*vide* the final paragraph of this Memorandum).

V.—TREATMENT OF THE SUPPURATION WHICH WILL SUPERVENE UPON THE LAYING OPEN OF WOUNDS AND INFECTED TISSUES.

The laying open of the wound or the infected tissue effects, as consideration will show, only the conversion of a more into a less dangerous form of infection, and we are, after our operative procedures, faced with a suppurative infection of our open wound and of our superadded incisions, and have now to check that infection.

It will in practically every case be an infection by the streptococcus combined with staphylococcus. And in very many cases there will be a superadded infection by coliform organisms, in particular by the bacillus proteus.

The therapeutic methods which we have here at disposal are the following:—

(1) *Provision of Satisfactory Drainage and Lymph Lavage.*

The first and most important thing will be to provide in the dependent portion of the wound a free outlet for the discharges and to secure, when we are dealing with infiltrated wound surfaces, a free outflow of lymph (*vide* Section IV.).

If, by either of these methods or by a combination of the two, we succeed in providing effective lymph lavage for our wound, we shall have very little difficulty with the infection.

But it will in a very large proportion of cases be quite impracticable to obtain all that would be desirable in the matter of drainage, and it is all-important to recognise in connexion with these cases that "conservative surgery," as applied to the wounded, means making, for the purpose of conserving a limb, legitimate sacrifices with respect to drainage. The question, and it is the most anxious and responsible question in all surgical procedures, as to how far one may sacrifice drainage, can only be arrived at by balancing in each particular case the advantage of preserving a limb against the risks of long-continued suppuration and eventual septicæmia.

We require here to have clear conceptions as to what amount of help is obtainable, on the one hand, from *vaccine-therapy*, from the employment of *antiseptics* in the wound, and from *frequent dressings*.

(2) *Vaccine-Therapy in its Application to Suppurating Wounds.*

It is important in connexion with this method of treatment to realise (*a*) that it aims at increasing the antibacterial powers of the blood, and (*b*) that the conditions which determine our success or failure are essentially the same when we employ vaccines as when we set ourselves to combat infections by the aid of the antibacterial power of the normal blood.

Ideally favourable conditions for the successful employment of a vaccine will be given when this is employed in treating a perfectly well-drained wound (let us say, such a wound as that furnished by a flapless amputation); or again, in treating an incursion of a microbe into a tissue where there is a very free lymph flow (let us say, such an infection as erysipelas). Here, by the use of an appropriate dose of the proper vaccine or vaccine mixture, successful results may be confidently expected.

The most unpromising cases for vaccine treatment are those where we are dealing with an unopened abscess sac, or a quite undrained wound, or an old-standing cicatrised tissue infection. Here the microbes are shut off from the blood fluids, and in these cases the utmost we have any right to expect is to prevent an extension of the infection and to ward off septicæmic complications.

In the case here specially in view, that of the imperfectly drained wound, we may expect to obtain by the repeated inoculation of the appropriate dose of the proper vaccine or vaccine mixture, not anything in the nature of dramatic results, but a certain improvement in the local conditions, together with a certain protection against septicæmia.

We may, in short, expect from vaccine-therapy results which will make it possible to employ conservative methods in a larger proportion of cases; to hold on longer to these methods; and to carry them oftener to a successful issue. It would therefore be advisable to carry out vaccine-therapy as part of the routine treatment of suppurating wounds. (*Vide* Instructions issued with Antisepsis Vaccine.)

(3) *Employment of Antiseptics in Wounds.*

It is notorious that the results of the treatment of suppurating wounds by antiseptics are disappointing, and that the reasoning which led to the universal adoption of this therapeutic method was, in point of fact, too unsophisticated.

It was tacitly assumed of chemical agents which acted as antiseptics in watery solution that they would do so also in blood fluids and pus; and that they would also penetrate a certain distance into the tissues and into blood clots. We know now that antiseptics do in these respects very much less than was anticipated.

It was further tacitly assumed that an antiseptic which gave good results with one particular microbe or group of microbes ought to give good results indiscriminately with all. But it is possible that particular antiseptics may be appropriate to particular microbes and groups of microbes: that, for instance, such an antiseptic as peroxide of hydrogen, which has very little effect on ordinary pyogenic microbes, may be specially effective on anaerobic micro-organisms.

But, at any rate, the principle has emerged that in choosing our antiseptics and the strength in which these are to be used we ought to guide ourselves by actual experiments on wounds and on the microbes which come into consideration in connexion with those wounds. And it would be clearly inadmissible in choosing antiseptics for employment in projectile wounds to leave out of sight the fact that anaerobic microbes and their spores have to be dealt with, and that the antiseptics we employ ought to be competent to kill these.

Again, it is still tacitly assumed by practically everyone who employs antiseptics that even if treatment with an antiseptic effects only a partial sterilisation, such partial sterilisation will always be something to the good.

This amounts in point of fact to the assumption that by substituting a smaller for a larger sowing the number of microbes in a culture will always be sensibly reduced.

In reality this will depend upon two factors: (*a*) the nature of the culture medium, and (*b*) the shorter or longer period allowed for the cultivation.

When we are dealing with a culture medium which is ideally favourable to the multiplication of microbes, the smaller sowing will, after a short space of time, give exactly the same number of microbes as the larger.

When we have a culture medium in which microbes develop very slowly the smaller sowing will for a very long time give a correspondingly smaller number of microbes.

When a cultivation medium which is unfavourable to microbes is after a certain lapse of time converted into a medium which is favourable to them, it will not be the larger or the smaller sowing, but the date at which the character of the fluid changes which will govern the result.

We have now to apply these general principles to the case of the cultivation of microbes in wounds; and we may consider first the evolution of events in wounds treated without antiseptics, and then inquire in what respect the use of antiseptics could modify this evolution.

There will after washing out remain behind in every wound a certain quantity of pus. In one case it will be a question of minimal collections left in the shallow depressions of a granulating surface; in another a question of quite large collections held up in inaccessible pockets.

This residual pus will furnish the sowing of microbes, and a culture will be set going as soon as lymph begins to trickle into the wound.

But the new culture will start off very slowly. And for two reasons: first, because the lymph in the condition in which it exudes inhibits nearly all microbial growth; secondly, because we have in the lymph phagocytically active leucocytes.

For a certain time these natural checks of microbial growths will be maintained. The conditions will, however, when the lymph is fouled by an appreciable mixture of residual pus, change rapidly. Phagocytosis will be arrested, and the effused lymph will be transformed into a medium which will be eminently favourable to the multiplication of all manner of microbes. If we now wait for only a few more hours we shall have in the wound a very luxuriant growth.

Coming now to the question how good could come of the employment of antiseptics in wounds, we recognise, in the first place, that we might by these means achieve an appreciably smaller sowing of microbes. Further, it is conceivable that if we were to leave behind in the wound a sufficiency of antiseptic we might obtain from it such a reinforcement of the growth-inhibiting power of the lymph as should more than offset the setback inflicted by the antiseptic in paralysing the phagocytic action of the leucocytes. Lastly, it is possible that an antiseptic, left behind in the wound in sufficient quantity, might prevent the residual pus converting the lymph into a good nutrient medium.

In reality these possibilities do not amount to much. It is clear that that appreciably smaller sowing of microbes which we are working for would be realised only where the whole wound surface can be thoroughly washed with an antiseptic. But these are precisely the cases where the effect of a smaller sowing of microbes would not make itself very much felt, for where the wound is left practically free of residual pus the natural checks of microbic growth would be longest maintained.

With regard to the other possibilities, all that is necessary to say is that they must rank only as possibilities, and that up to the present experiment has not furnished anything in confirmation of the idea that the introduction of antiseptics into wounds would be likely to contribute to the arrest of suppuration.

It must, however, be emphasised, in conclusion, that in the treatment of the wounded in hospital it is essential to look beyond the individual to the aggregate. And even if it were finally to emerge that the employment of antiseptics did not do anything towards the arrest of suppuration in an infected wound, the taking of careful antiseptic precautions, and the washing out of the wound by antiseptic solutions, would none the less be indispensable. For if such precautions were omitted, infective microbes would inevitably be carried from one wound to another, and there would inevitably, by such "passaging," be bred out in hospital very virulent strains of microbes, which would, as in pre-Listerian days, induce all manner of fatal septic infection.

(4) *Frequent and Efficient Dressing of the Wound.*

Coming back from this general consideration to the question of the treatment of the individual infected wound, it will be clear from what has been said above that the frequent and efficient washing out and dressing of the wound will be a factor of dominating importance in the treatment of the infection. Where comparatively long intervals intervene between the dressings, where pus is left behind in the wound, where the discharges are confined by plugs or multiple folds of dressing, and where, in the case of a deep wound, too small drainage-tubes are employed little or no progress will be made. Where large drainage-tubes are employed, where the wound is frequently washed out, where no pus is left behind, and where only a very light dressing is employed, we shall be making progress.

And clearly, so long as a wound is heavily infected, the ideal method of treatment, if only it were always practicable, would be immersion in a bath or continuous irrigation with some aseptic or mildly antiseptic fluid.

When the continuous bath or, as the case may be, lymph lavage induced by hypertonic salt solution has brought the infection under control, what remains of that infection may very often be extinguished by freely exposing the open wound to the air. The part which the drying off of the wound surfaces and the concentration of the discharges plays in the killing off of the residual microbes has not yet been investigated.

NOTE.—The recommendations with regard to surgery which are put forward in the Memorandum have been formulated in consultation with Colonel Sir B. Moynihan and Colonel F. F. Burghard.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Death of Captain John Esmonde, R.A.M.C., M.P.

Captain John Esmonde, Member of Parliament for North Tipperary, died on April 17th from pneumonia, after a few days' illness. He was the son of the late Mr. James Esmonde, J.P., of Drominagh, co. Tipperary, and was educated at Clongowes and Stonyhurst, and subsequently in the school of the Royal College of Surgeons in Ireland. He obtained the Licence of the College in 1884, and in 1891 he became a Licentiate of the Apothecaries' Hall. He practised in various districts in England for some 24 years and then returned to his native county. In 1910 he was elected to Parliament as a member of the Irish Nationalist Party. After the outbreak of the war he accepted a captain's commission in the Royal Army Medical Corps, and was given duty in Ireland. Though of late years his activities were rather political than professional, he did not lose his professional interests. During the passage of the National Insurance Act through the House of Commons he gave cordial help to his professional brethren, who will join with his political colleagues in regret at his early death. He was only 52 years of age.

The Women's National Health Association.

The annual conference of the Women's National Health Association was held last week in Dublin under the presidency of Lady Aberdeen. Discussions took place on the medical inspection of school children, infant mortality, and kindred subjects, and reports were submitted dealing with the various activities of the association.

Cerebro-spinal Meningitis.

Dr. A. Gardner Robb, medical superintendent of Purdysburn Municipal Fever Hospital, Belfast, has issued a circular to the medical practitioners of Belfast urging the importance of early serum treatment in cerebro-spinal meningitis. He appeals to them to send any cases they may wish to have treated in hospital at the earliest possible moment. He quotes Flexner's collected cases, which show that among those injected with serum between the first and third day of illness the mortality was 16·5 per cent., while if they were injected between the fourth and seventh day it was 23·8 per cent., and after the seventh day the mortality was 35 per cent. In 275 cases in the Belfast fever hospitals before the use of serum the mortality was 72·3 per cent. In 117 cases treated with the serum the mortality has been just under 24 per cent. In the present outbreak of cerebrospinal meningitis 24 cases were admitted from the city of Belfast; while some of these were sent in quite early, on an average they had reached, when admitted, the fourth day of the disease. Had they been all sent in early the death-rate, Dr. Robb thinks, would have been improved.

A Dispensary Doctor Volunteers.

The Ballymena board of guardians have decided to allow Mr. Alexander Duncan, L.R.C.P. & S. Edin., J.P., medical dispensary officer of Glenwherry district of the Ballymena union, to proceed for military duty at the seat of war, to keep his position open for him, and to pay for a locum-tenent during his period of service.

April 19th.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Reform of the Sanitary Service in France.

THE Minister for War has made important reforms both in the personnel and in the organisation of the sanitary service. The region is divided into 21 districts, each of which will in future be under the care of an inspector-general. Dr. Février, who was director of the sanitary service of the trenches around Paris and who has been replaced by Médecin Inspecteur Dziewonski, has been appointed inspector-general of the 4th District at Mans. Dr. Vaillard, former director of the technical committee, has been appointed inspector-general of the Paris district. The Minister for War looks for increased efficiency of the services from this new organisation.

A Japanese Hospital in Paris.

A Japanese detachment of the Red Cross arrived in Paris some weeks ago under the charge of Professor Shiota. The Hotel Astoria in the Champs Elysées has been placed at his disposal. With great promptness 150 beds were installed and are tended by the 21 attendants who accompanied Professor Shiota. The inauguration ceremony was presided over by M. Troussaint, director of the sanitary service at the Ministry of War, accompanied by the Japanese Ambassador.

Window-blind Splints for Fractures.

Dr. Prestrelle, having occasion to put up a very large number of fractures in soldiers, has devised an emergency method for their reduction which has given him excellent results in securing the removal of the wounded to the ambulance or the field hospital with a minimum of suffering and danger from complications. Having frequently found it necessary to insert in the plaster casing, to increase its firmness, pieces of green window-blind (*stores verts*)—blinds, that is, composed of fine fibres of rush held together by latticed threads—it occurred to him to make use of them as splints (without using the plaster). While very rigid in the longitudinal direction they can be made to adapt themselves in the other direction to any surface as desired. With strong scissors they can be cut into the exact length and shape necessary. For a fracture of the leg, after an aseptic dressing of the wound, the limb is surrounded with a good layer of cotton wool, then a piece of blind extending two centimetres below beyond the heel and reaching above to the upper third of the thigh is applied. A roller bandage applied around the thigh to the top of the apparatus and a stirrup spiral wound round the foot secure immobility. For the thigh, in like manner, the blind material is cut so that it reaches the fold of the groin internally and the great trochanter externally, starting from the heel. In fractures of the thigh, when once the patient has been comfortably settled on the stretcher, Dr. Prestrelle attaches a weight or a brick to the foot by means of a cord passing over another cord joining the two handles of the stretcher. He has thus been enabled to keep for a day and a night at the dressing station wounded men with fractured thighs almost entirely free from suffering.

April 19th.

KING EDWARD'S HOSPITAL FUND FOR LONDON.

THE annual meeting of the Governors and General Council of King Edward's Hospital Fund for London was held under the chairmanship of the SPEAKER of the House of Commons at St. James's Palace on April 19th, when the accounts and report of the General Council for the year 1914 were presented.

Sir SAVILE CROSSLEY read a letter from Lord Stamfordham in which the King expressed his deep sense of the loss sustained by the Fund in the death of Lord Rothschild, the honorary treasurer and chairman of the Finance Committee, and cordially approved of the action of the Governors in appointing Lord Revelstoke as Lord Rothschild's successor.

On the motion of the SPEAKER, seconded by Lord IVEAGH, a resolution expressing profound regret at the death of Lord Rothschild was unanimously carried.

The SPEAKER then announced the following appointments: The Hon. Algernon H. Mills, who was already on the Finance Committee, to be a member of the Council, and the Hon. Nathaniel Charles Rothschild to be a member of the Finance Committee, after which

Lord REVELSTOKE presented the accounts for 1914, which were unanimously adopted.

Sir SAVILE CROSSLEY submitted the draft report of the Council, which stated that the total receipts for the year 1914 were £529,885 14*s.* 3*d.*, of which £315,093 10*s.* 11*d.* were contributions to capital, and £214,792 3*s.* 4*d.* receipts on general account. The amount distributed was £140,000, as against £157,500 in the previous year. Although the total distributed was less than in 1913, there was an increase in grants in aid of the ordinary maintenance of hospitals, the reduction being wholly accounted for by a diminution in the claims on the Fund for building expenditure. This diminution was due to the postponement by the hospitals at the outbreak of the war of all schemes not actually in hand or particularly urgent. Of the sum of £140,000 distributed the hospitals received £133,500, the remaining £6500 being distributed amongst consumption sanatoriums and convalescent homes taking London patients. The £133,500 allotted to the London hospitals was directed to be applied as follows: £108,550 to general purposes and maintenance, £12,600 towards the liquidation of debts on maintenance account, and £12,350 for additions and improvements to hospitals and their equipment. Of the £6500 given to consumption sanatoriums and convalescent homes, £3800 were allotted in consideration of the allocation of beds for patients to be sent from certain London hospitals. Since the foundation of the Fund a total amount of

£1,930,416 8*s.* 5*d.* has been distributed—an average annual distribution of £107,245 7*s.* 2*d.* The contribution of the League of Mercy this year had again reached £14,000. With regard to the future needs of the Fund, the report states that the sum required to be raised during the year, after taking into account income from investments, in order to maintain the distribution of £140,000, will be nearly £60,000; while to reach again the distribution of the three previous years more than £75,000 must be obtained in the year by means of annual subscriptions, donations, and legacies. The total amount received from annual subscriptions and donations during 1914 showed, as compared with 1913, a decrease of £750, while the receipts from legacies (other than the Lewis and Harman bequests) were £19,525 less than the previous year, or £6223 less than the average of the five years 1909 to 1913. The nation, the report continues, will surely realise that the work done by the hospitals, both in the treatment of the wounded and in the providing and training of doctors, nurses, and administrators in the medical service of the army and navy, gives them a special claim on the generosity of the public. The Council view with great satisfaction the successful amalgamation of the Hospital for Diseases of the Throat, Golden-square, and the London Throat Hospital, Great Portland-street.

The SPEAKER moved the adoption of the report, which was seconded by Dr. FREDERICK TAYLOR, the President of the Royal College of Physicians of London, and adopted unanimously.

Other business having been transacted, the meeting terminated.

THE MEDICAL MAN'S INCOME-TAX.

As the season has arrived for the completion of the annual income-tax return, this year to be the basis of a charge at the highest rate ever imposed, the moment is opportune for an explanation of the manner in which the sum to be returned by the practitioner should be arrived at. Official instructions are, it is true, issued with the forms, but to the average professional man they appear to be designed to meet every case but his own.

Repayment of Excess Tax.—Calculation of "Earnings."

It may be remarked in the first place that the past year, 1914-15, is not a closed book so far as the tax is concerned if the profits of a practice have fallen from some cause connected with the war. In such a case an application for repayment of the excess tax may be made to the local surveyor of taxes; but tax will be repaid only on the amount by which the assessment exceeded the average of the profits of the three years, 1912, 1913, and 1914, unless the practitioner has himself been serving in connexion with the war, when the profits of the year 1914 will be taken. Service in connexion with the war includes for this purpose work abroad on behalf of the Red Cross Society, the St. John Ambulance Association, or similar body. In one other case also adjustment may be claimed—that is, where the profits have fallen on account of a change in the ownership of a practice or in the members of a partnership.

The sum to be returned under "Schedule D" is, broadly speaking, the amount of the earnings of the practice after deducting the professional expenses, on the average of the three years 1912, 1913, and 1914 (which may be taken as ending on Dec. 31st, 1914, March 31st, 1915, or other date before March 31st, to which the accounts are usually made up). The "earnings" should in strictness be the fees arising in the course of each year, but it is a recognised custom to take the more convenient basis of the sums actually received each year, a system which obviates the necessity of entering into questions as to the amount of bad debts. It is only in the case of new practices, where the receipts in the first two or three years are not a proper index of the earnings in those years, that the revenue authorities take exception to this system. Where public appointments are held as an addition to a practice a separate return for each under "Schedule E" is usually called for on a blue form, but it is not necessary to make these separate returns if the profits from the appointments are included in the general return of average profits. This course renders unnecessary not only the completion of several returns, but also the separate calculation of expenses for each office and payment of tax on separate assessments, perhaps to various collectors; but care should be taken to send back the blue forms with a note of the address from which the inclusive return has been made. Under this system the income from a new appointment is not returned until it comes into the three years taken for an average. Sums received under the National Insurance Act are in any case regarded as ordinary receipts of the practice.

Expenses.

The expenses that may be deducted from the profits of each year may be summarised as follows:—

Rent, rates, and taxes.—The full amount for premises not used as a dwelling, and up to two-thirds where only partly used for professional purposes. If the practitioner is the owner of his house two-thirds of the income-tax valuation (Schedule A) should be deducted in lieu of rent. Inhabited-house duty may be included in the "taxes," but not income-tax.

Car and carriage expenses, including upkeep, repairs, petrol, licence, car insurance, garage and stable expenses, harness, fodder, veterinary surgeon's bill, and also the cost of replacing car, carriage, or horses. The cost of replacement is required to be based on the sum originally paid for the article replaced unless the sum paid for renewal be less.

Salaries, wages, and board of assistants, chauffeur or coachman, domestic servants, and other employees. In the case of servants occupied partly in household duties an apportionment should be made. The cost of board is usually taken at about 10*s.* a week and where an outside lodging is provided for any servant the actual expense incurred should be added.

House expenses, including fuel, lighting, repairs, decorations, &c. In the ordinary case it will be necessary to estimate the proportion of these expenses properly attributable to the portion of the house used for professional purposes.

Sundry expenses.—Insurance of servants (employer's liability and Government insurance), special travelling expenses, cost of instruments, books, professional papers, telephone, postages, stationery, and other incidental expenses.

Locum-tenents.—Sums paid to locum-tenents are usually allowed where the recipient is exempt from income-tax or makes his own return, but the expense is frequently disallowed when incurred for the purpose of taking a holiday.

Among the outgoings that are not allowed in computing the profits may be mentioned the purchase of a practice, whether in one sum or by instalments, annuities paid to former practitioners or their widows, sums expended in the setting up of a practice or in the extension of premises, the cost of a first car or carriage, interest on loans, life or sickness assurance premiums, voluntary subscriptions, and, generally expenses not incurred for professional purposes. It is to be observed, however, that in the case of interest and annuities income-tax should be deducted from the payments, so that these outgoings are in effect allowed, and life assurance premiums are treated as a deduction from the assessment. Bank interest on a loan for professional purposes is an exception to the general rule for interest and may be charged as an expense. No sums drawn in the way of salary or interest on capital may be deducted, such sums being regarded as part of the income.

The question of an allowance for the yearly depreciation of motor-cars is a somewhat sore point. The revenue authorities, taking advantage of the fact that the Act allowing depreciation was passed at a time when the use of "machinery" in connexion with a profession (as distinct from a trade) was not contemplated, refuse to make any allowance under this head to others than traders. It is therefore only by means of charging the cost of replacing the car when worn out that the practitioner can in effect obtain reduction on account of the decrease in value year by year.

A further article will deal with the various descriptions of relief that may be claimed and with the manner in which the form of return should be completed to insure all allowances that may be due.

(To be concluded.)

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned have been granted temporary commissions as Staff-Surgeons in His Majesty's Fleet:—Dated April 14th: Arthur Edmunds. Dated April 15th: Charles Harley Savory and John Greenlaw Dobson. Dated April 16th: Ralph Burn Boston and Charles Joseph Thompson.

The undermentioned has been granted a temporary commission as Surgeon in His Majesty's Fleet: William Leckie Coullie (dated April 12th).

The following appointments have been notified:—Temporary Surgeons: W. L. Coullie, G. R. Stathers, and C. H. Savory, all to the *Victory*, additional, for Haslar Hospital; G. R. T. Thomson and J. G. Dobson to the *Pembroke*, additional, for Chatham Hospital; and R. B. Boston and C. J. Thompson, both to the *Vivid*, additional, for Plymouth Hospital.

ROYAL ARMY MEDICAL CORPS.

The undermentioned temporary Lieutenants to be temporary Captains: Augustus W. Addinsell, Leonard B. Cane, late Captain, Royal Army Medical Corps, Territorial Force Reserve.

Temporary Lieutenant Frederick J. Stephenson relinquishes his commission (dated April 3rd).

ARMY SERVICE CORPS.

Lieutenant Ernest A. Greenwood, Royal Army Medical Corps (Territorial Force), to be temporary Lieutenant.

INDIAN MEDICAL SERVICE.

The King has approved the promotion of the following officers:—Majors to be Lieutenant-Colonels: Dated Jan. 29th: Algernon Francis Stevens, Clement Henry Bensley, Francis Hammond Watling, Brevet Lieutenant-Colonel Frank Wall, Charles Montague Mathew, John Stephenson, Frank Needham Windsor, Ernest Edwin Waters, Asher Leventon, Arthur Frederick William King, Robert Frazer Standage, Andrew Armstrong Gibbs, Edmund Moritz Illington, and Charles George Webster.

The King has approved the retirement of the undermentioned officer: Major Walter Hulbert Cox, D.S.O.

TERRITORIAL FORCE.

Army Medical Services.

Major Frederick R. Miller, from 3rd London General Hospital, to be Deputy Assistant Director of Medical Services, 2nd London Reserve Division.

Royal Army Medical Corps.

1st South Midland Field Ambulance: Edmund Whichello to be Lieutenant.

3rd West Riding Field Ambulance: Captain William S. Kerr to be temporary Major.

3rd London General Hospital: Wilfred Batten Lewis Trotter and Hugh Morrison Davies to be Captains, whose services will be available on mobilisation.

1st Northern General Hospital: The undermentioned to be Lieutenants: Norman Hodgson, Frederick John Nattrass, Thomas Whitelaw, and Sydney Thompson.

2nd Southern General Hospital: The undermentioned to be Captains, whose services will be available on mobilisation: John Alexander Nixon (late Captain of this Unit), John Roger Charles (late Lieutenant, 1st South Midland Brigade, Royal Field Artillery), Charles Ferrier Walters (late Lieutenant, 3rd South Midland Field Ambulance), Clifford Arthur Moore, Arthur Rendle Short, and Arthur Launcelot Flemming (late Major of this Unit).

2nd London Sanitary Company: Sidney Herbert Daukes to be Lieutenant (dated March 2nd, 1915).

East Anglian Casualty Clearing Station: Major Francis J. Warwick, from Attached to Units other than Medical Units, to be Major, with precedence as in the Territorial Force.

West Riding Casualty Clearing Station: The undermentioned Lieutenants, from the 2nd West Riding Field Ambulance, to be Lieutenants (dated Dec. 31st, 1914): Robert G. Dixon and Hubert W. Symons.

2nd Northumbrian Field Ambulance: William Arthur Benson (late Captain, 8th Battalion, The Durham Light Infantry) to be Lieutenant-Colonel (temporary). John Percy Race to be Lieutenant.

3rd Northumbrian Field Ambulance: Captain Arthur Tinley Sissons, from the Territorial Force Reserve, Royal Army Medical Corps, to be Captain (temporary).

3rd London General Hospital: The undermentioned to be Captains, whose services will be available on mobilisation: Gwynne Evan Owen Williams and Charles Aubrey Pannett.

Eastern Mounted Brigade Field Ambulance: Captain Claudius G. K. Sharp to be temporary Major.

Highland Mounted Brigade Field Ambulance: David Dunn Mackay to be Lieutenant.

3rd Lowland Field Ambulance: George James Linklater to be Lieutenant.

3rd South Midland Field Ambulance: David McVea Fleck to be Lieutenant.

1st Eastern General Hospital: Major Laurence Humphry to be temporary Lieutenant-Colonel.

1st London (City of London) General Hospital: William Farrer Thompson to be Lieutenant.

4th London Field Ambulance: Major Mowbray Taylor, from the 5th London Field Ambulance, to be Lieutenant-Colonel (temporary).

Sanitary Service: Captain Robert Proudfoot, from Attached to Units other than Medical Units, to be Sanitary Officer, Welsh Territorial Division. Frederick Thomas Churchill Linton to be Captain, whose services will be available on mobilisation.

North Midland Casualty Clearing Station: Henry Crook Bevan to be Lieutenant.

Attached to Units other than Medical Units.—To be Lieutenants: Robert Lucius Wood, Lieutenant John S. Hall, from the 3rd West Riding Field Ambulance, and Sidney Hughes.

DEATHS IN THE SERVICES.

Surgeon-General Aylmer Martin Crofts, C.I.E., I.M.S., suddenly, at the Naval and Military Hotel, London, on April 12th. He was born in 1854, and was the son of George Crofts, Esq., of Temple Hill, Blackrock, Cork. He qualified as L.R.C.S. Edin. in 1876 and L.R.C.P. Edin. in 1877, and entered the Indian Medical Service in the same year. He served in the Afghan War of 1878–80 (obtaining the medal), the Egyptian War of 1882 (gaining the medal with clasp and receiving also the Khedive's star), and in the Zhob Valley Expedition of 1884. In 1886 he was appointed residency surgeon at Gwalior, and the young Maharajah was placed in his charge. During the China Expedition of 1900–01 he was senior medical officer of the hospital ship *Gwalior*. In 1905 he became agency surgeon at Kotah and Thalawar, and later in the year he was appointed to the North-West Frontier Provinces. In 1900 he received the C.I.E.; he was also an Honorary Associate of the Order of St. John of Jerusalem.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 9540 births and 6618 deaths were registered during the week ended Saturday, April 17th. The annual rate of mortality in these towns, which had increased from 19·3 to 19·9 per 1000 in the four preceding weeks, fell, in the week under notice, to 19·0 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of last year. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 19·6, against a corresponding rate of 20·6 per 1000 in London. Among the several towns the death-rate last week ranged from 9·0 in Wallasey, 9·5 in Edmonton, 10·2 in Enfield, 10·4 in Walthamstow, and 10·5 in Darlington, to 26·2 in Wigan, 26·7 in Carlisle, 26·8 in Middlesbrough, 29·5 in South Shields, and 30·8 in West Hartlepool.

The 6618 deaths from all causes were 304 fewer than the number recorded in the previous week, and included 736 which were referred to the principal epidemic diseases, against 826 and 767 in the two preceding weeks. Of these 736 deaths, 426 resulted from measles, 151 from whooping-cough, 63 from infantile diarrhœal diseases, 55 from diphtheria, 28 from scarlet fever, 11 from enteric fever, and 2 from small-pox. The mean annual death-rate from these diseases was equal to 2·1, against 2·2 per 1000 in the previous week. The deaths attributed to measles, which had been 397, 495, and 452 in the three preceding weeks, further declined to 426 last week, and caused the highest annual death-rates of 3·3 in Wolverhampton, 3·6 in Salford, 3·9 in Walsall, 4·0 in West Hartlepool, 4·3 in Merthyr Tydfil, 4·6 in Northampton, 5·3 in Coventry, 5·9 in Hornsey and in Carlisle, and 8·3 in West Bromwich. The deaths referred to whooping-cough, which had been 127, 157, and 167 in the three preceding weeks, fell to 151 last week; the highest recorded death-rates from this cause were 1·2 in Blackburn, 1·7 in Southampton, 1·8 in Merthyr Tydfil, 2·1 in Bootle, 2·4 in West Hartlepool, 2·5 in Tynemouth, 2·9 in Barnsley, 3·0 in Carlisle, and 6·8 in Wigan. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 70, 77, and 67 in the three preceding weeks, further fell to 63 last week, and included 18 in London, 4 each in Liverpool and Manchester, and 3 each in Birmingham, Oldham, and Middlesbrough. The deaths attributed to diphtheria, which had been 58, 69, and 49 in the three preceding weeks, rose to 55, of which 12 occurred in London, 4 each in Birmingham and Liverpool, and 3 in Manchester. The deaths referred to scarlet fever, which had been 31, 16, and 25 in the three preceding weeks, further rose to 28 last week, and included 9 in London, 3 in Liverpool, and 2 each in Oldham and Preston. The fatal cases of enteric fever, which had declined from 15 to 7 in the five preceding weeks, rose to 11 last week, of which 2 were recorded in Plymouth and 2 in Salford. The 2 deaths from small-pox were registered in Bristol.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5036 to 2505 in the 20 preceding weeks, had further declined to 2422 on Saturday last; 263 new cases were admitted during the week, against 301, 253, and 275 in the three preceding weeks. These hospitals also contained on Saturday last 1281 cases of diphtheria, 378 of measles, 621 of enteric fever, and 16 of whooping-cough, but not one of small-pox. The 1761 deaths from all causes in London were 63 fewer than in the previous week, and corresponded to an annual death-rate of 20·3 per 1000. The deaths referred to diseases of the respiratory system, which had been 481, 475, and 466 in the three preceding weeks, rose to 469 in the week under notice, and were 206 in excess of the number in the corresponding week of last year. The deaths from influenza numbered 39, against 65, 45, and 46 in the three preceding weeks.

Of the 6618 deaths from all causes in the 96 towns 198 resulted from different forms of violence and 436 were the subject of coroners' inquests, while 1849 occurred in public institutions. The causes of 51, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in London and in its 14 suburban districts, in Sheffield, Leeds, Bristol, Bradford, and in 51 other smaller towns. Of the 51 uncertified causes, 9 were registered in Birmingham, 8 in Liverpool, 3 each in Manchester and Gateshead, and 2 each in Bury, Hull, Sunderland, Newcastle-on-Tyne, Tynemouth, and Carlisle.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland with an aggregate population estimated at 1,212,380 persons at the middle of this year, 701 births and 515 deaths were registered during the week ended Saturday, April 17th. The annual rate of mortality in these towns, which had been 23·9, 22·9, and 23·8 per 1000 in the three preceding weeks, fell to 22·1 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 25·4, against corresponding rates of 19·6 and 22·4 per 1000 in the English and Scotch towns respectively. The death-rate last week was equal to 24·1 in Dublin (against 20·3 in London and 22·1 in Glasgow), 21·5 in Belfast, 25·8 in Cork, 12·7 in Londonderry, 13·5 in Limerick, and 22·8 in Waterford, while in the 21 smaller towns the mean rate was 21·7 per 1000.

The 515 deaths from all causes were 38 fewer than the number in the previous week, and included 30 which were referred to the principal epidemic diseases, against 37 and 40 in the two preceding weeks. Of these 30 deaths, 11 resulted from whooping-cough, 5 each from measles, scarlet fever, and infantile diarrhœal diseases, 3 from diphtheria, and 1 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 1·3, against 2·1 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had been 16, 13, and 15 in the three preceding weeks, fell to 11 last week, and included 5 in Belfast and 4 in Dublin. The deaths referred to measles, which had been 12, 7, and 16 in the three preceding weeks, declined to 5 last week, of which 3 were recorded in Belfast. The 5 fatal cases of scarlet fever were slightly in excess of the average in recent weeks, but showed no excess in any particular town. The deaths of infants (under 2 years) from diarrhœa and enteritis, which had been 11, 11, and 3 in the three preceding weeks, rose to 5 last week, and comprised 3 in Dublin and 2 in Belfast. The fatal cases of diphtheria were registered in Dublin, Belfast, and Dundalk respectively, and that of enteric fever in Belfast.

The deaths referred to diseases of the respiratory system, which had been 145, 121, and 158 in the three preceding weeks, fell to 119 in the week under notice. Of the 515 deaths from all causes, 159, or 31 per cent., occurred in public institutions, and 10 resulted from various forms of violence. The causes of 15, or 2·9 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the large English towns the proportion of uncertified causes did not exceed 0·8 per cent.

THE Hospital for Consumption and Diseases of the Chest, Brompton, at which special arrangements have been made for the admission of sailors and soldiers of the Allied Forces suffering from consumption, has received a special donation of £1000 from a gentleman who desires to remain anonymous.

"Audi alteram partem."

ACHOLURIC JAUNDICE.

To the Editor of THE LANCET.

SIR,—The interesting case of acholuric jaundice reported by Dr. W. Harmens in your issue of April 10th (in which it is to be hoped that removal of the spleen may be attended with permanent relief) is doubtless characterised by the usual difficulties which such cases present. In connexion with Dr. Harmens's case, one may well consider the case of Dr. T. R. C. Whipham, fully described in THE LANCET of Nov. 21st, 1914. In Dr. Whipham's case there was bile pigment in the urine and an absence of urobilin, and owing to this exceptional circumstance Dr. Whipham thinks the name of the affection ought to be altered. Now the recent experimental work of Whipple and Hooper[1] seems to have solved one of the main difficulties in connexion with these perplexing cases. These investigators have proved that hæmoglobin can be transformed into bile pigment in the circulation and a true hæmatogenous jaundice induced. Those interested may refer to the original paper. Briefly put, after the production of an Eck fistula and ligation of the hepatic artery, the hæmoglobin of red cells injected into the blood is rapidly changed into bile pigment. When the liver, spleen, and intestines were shut out from the circulation, and a head and thorax circulation only existed, the same thing occurred. The authors consider that the endothelial cells of the blood vessels and other organs can transform the hæmoglobin into bile pigments. In "acholuric" jaundice, therefore, the presence or absence of pile pigment in the urine is non-essential and depends on the amount in circulation.

These observations not only throw some light on acholuric jaundice, but they clear up certain doubts in regard to hæmatogenous jaundice in general. I may perhaps be excused in mentioning that in 1896 I upheld by experimental work the theory of a hæmatogenous jaundice in a paper read before the British Medical Association.[2] I showed that in certain cases the liver might be rendered incapable of secreting bile, but that bile pigments were nevertheless found in the urine, and traced these pigments to hæmolysis by the spleen. The hæmolysis in acholuric jaundice is probably brought about by disturbance of the lipoid envelope of the red corpuscle by a toxic or emulsifying substance, present in the spleen.

I am, Sir, yours faithfully,

Harley-street, W., April 12th, 1915. A. G. AULD.

MENINGOCOCCUS AND DIPHTHERIA CARRIERS.

To the Editor of THE LANCET.

SIR,—With reference to the collection of material from the naso-pharynx uncontaminated by oral organisms, this can be readily made by using a post-nasal cannula which I introduced many years ago and find to be of much practical value.

It consists of glass tubing (10 mm. diameter) bent at a right angle to admit of passage below soft palate into the post-nasal space. Through it a wire charged with wool can easily be passed. It is quickly and cheaply made by bending a length of glass tubing in the gas flame and then cutting to the desired length (long arm 6 in., short arm ¾ in.) A tongue depressor will help, but it is not essential with an intelligent patient. If used, it may either be removed after introducing the cannula or transferred to the patient's hand. Should the patient prove to be "intolerant" a slight preliminary application of cocaine to the faucial ring is advisable. A drawing of the cannula will be seen in "Diseases of the Ear," Milligan and Wingrave, p. 58 (Macmillan, 1911).

---

[1] Journal of Experimental Medicine, June 1st, 1913, p. 612.

[2] Brit. Med. Jour., vol. i., 1896, p. 137.

The present importance of the matter is my only reason for drawing attention to a very simple method which personal experience has proved to be of the greatest assistance in identifying meningococcus and diphtheria carriers.

I am, Sir, yours faithfully,
WYATT WINGRAVE, M.D. Durh.,
Pathologist, Central London Throat and Ear Hospital.
Bloomsbury-square, W.C., April 14th, 1915.

STOMACH *V.* HEART IN RELATION TO PRÆCORDIAL PAIN AND SUDDEN DEATH.

To the Editor of THE LANCET.

SIR,—I have read with interest Sir Clifford Allbutt's letter in THE LANCET of April 17th in which he suggests that the case described by Dr. Edgar Lea is "one of syphilitic aortitis with angina and needs no particular 'segmental' or other 'neurosis' to explain it." He speaks of the algesic symptom as of "no clinical use." But algesia, which Sir Clifford Allbutt dismisses as of "no clinical use," has, I think, a way of cropping up in every case of the angina pectoris. In cases in which at first sight I have thought it to be absent, it has revealed itself on closer examination or at a later time. Moreover, the symptom displays distinctive peculiarities. It is fitful in its incidence. One day it apoears at the epigastrium, upon another in cervical or brachial regions, and on a third perchance in isolated patches scattered over superficial and deep structures of the thoracic walls. Sometimes the symptom is accompanied by rigidity of muscle and pain, at other times it appears alone. Certain authorities agree in regarding intercostal algesia which appears in connexion with gastro-intestinal troubles as indicating the existence of foci of irritation at spinal centres. Among these I may mention Dr. Head, Dr. James Mackenzie, Dr. Hertz, Sir Bertrand Dawson, and, as a pioneer in this subject, Professor Langley. Further, in the case of the angina pectoris Dr. James Mackenzie and the late Professor G. A. Gibson have referred to the neurosis as secondary to myocardial disorder and as produced by it.

The object of my letter in your issue of April 3rd was to suggest that sufficient grounds exist for singling out this fitful neurosis as the predisposing cause of the angina pectoris and for ascribing it to long-continued gastro-intestinal hypertension or irritation. In this scheme of causation myocardial disturbance is regarded as of secondary significance and as indeed occupying the status of an attendant symptom, or at most that of a remote causal factor, perchance operative in a limited proportion of cases.

I am, Sir, yours faithfully,
H. WALTER VERDON.
Streatham Hill, S.W., April 19th, 1915.

CEREBRO-SPINAL MENINGITIS: MENINGOCOCCI FOUND IN PERIPHERAL BLOOD FILMS.

To the Editor of THE LANCET.

SIR,—I read with interest in your issue of April 10th the account by Dr. Alfred C. Coles of a case of cerebro-spinal meningitis of septicæmic type. What struck me was the absence in this account of any definite evidence that this case was really one of meningococcal infection. From the clinical point of view the report states that there were "no signs or symptoms to indicate the presence of meningitis." The cytological and bacteriological examination of the cerebro-spinal fluid was negative as far as the meningococcus was concerned. The examination of blood films (blood cultures are not mentioned) revealed the presence of cocci morphologically resembling gonococci, but no mention is made of any distinctive staining method having been used as a means of helping in the identification of the cocci; and I have noticed that cocci, such as ordinary staphylococci, which appear as circular cocci if stained by Gram's method with aniline-oil-gentian-violet, often appear as "bean-shaped" cocci, resembling gonococci, when stains of the Giemsa type are used.

When an account of the various forms of meningococcal infection that have occurred during the present epidemic of the disease comes to be written, such cases as the one under consideration will perhaps be cited as evidence of blood-stream infection with the meningococcus, although the clinical and bacteriological evidence brought forward may leave much to be desired, and may falsify statistics for which they may be used. It is obviously desirable, then, that in reporting such cases well-recognised reactions of the organism should as far as possible be looked for and reported on as positive or negative.

I am, Sir, yours faithfully,
E. L. HUNT.
Bacteriological Laboratory, St. George's Hospital, S.W., April 16th, 1915.

CERTAIN PECULIAR CRYSTALS FOUND IN CEREBRO-SPINAL FLUID.

To the Editor of THE LANCET.

SIR,—In your issue of April 3rd a letter from Mr. Ernest H. Shaw appeared in reference to my article on the above subject. In this letter he affirms that these crystals were altogether extraneous, and could be obtained by boiling tap water, allowing it to cool, and examining the deposit. He then goes on to state that in "films stained with carbol-fuchsin for tubercle bacilli the crystals retain some of the stain." The crystals I described (as I pointed out) are readily soluble in dilute acids, and therefore on examining a film after the usual Ziehl-Neelsen technique no trace whatever of the crystals remains. I have, naturally, in the ordinary course of my work boiled many bottles, syringes, centrifuge tubes, &c., in tap water, but never have I found as a result crystals at all comparable to those I have described, nor have they previously been seen by any pathologist to whom I have shown them.

It is rather strange that in the same week as the article appeared in THE LANCET I again found identical crystals in a specimen of cerebro-spinal fluid removed by Professor Thomas Sinclair, of Belfast. After reading Mr. Shaw's letter I thoroughly washed the cork and bottle in which the cerebro-spinal fluid had been sent to me and asked Professor Sinclair to sterilise these again, which he did, using the same technique—water from the same tap and the same steriliser. I centrifugalised the contents of the bottle, but no crystals were found.—I am, Sir, yours faithfully,

Belfast, April 15th, 1915. W. W. D. THOMSON.

DIFFICULT LABOUR AND DENTAL DEFORMITIES.

To the Editor of THE LANCET.

SIR,—I have been for some time past investigating the relationship of difficult labour to dental deformities, and I am wondering whether you would allow me through your columns to appeal for assistance to your wide circle of readers. The cases of particular interest are those of delayed labour in face presentation, breech presentation, and delivery by forceps. I should be grateful for the details of such cases together with models of mouth showing the occlusion of the teeth.

I am, Sir, yours faithfully,

11, Queen Anne-street, W., April 18th, 1915. J. F. COLYER.

THE INHALATION OF CHLOROFORM IN BRONCHIAL CATARRH.

To the Editor of THE LANCET.

SIR,—During the past winter I have been called upon to treat a great many cases of post-influenzal bronchial catarrh accompanied by very troublesome cough occurring in violent paroxysms which are very exhausting for the sufferer. I find that a single deep inhalation of chloroform (from the bottle for instance), retained for a few seconds, almost invariably allays the sensation of tickling in the throat and secures immunity from recurrence for a certain period. I have extended this treatment to cases of phthisis and I find that here too the whiff of chloroform exerts a manifestly sedative action. The method is so simple and so effectual that I commend it for a trial, especially as there does not seem to be any drawback to this application of chloroform. I may mention incidentally that in cases where the cough shows a tendency to become troublesome as soon as the patient goes to bed it can often be cut short by lying prone for a minute or two, after which the lateral decubitus is cautiously resumed.

I am, Sir, yours faithfully,

ALFRED S. GUBB, M.D.Paris.

Aix-les-Bains, Savoie, April 13th, 1915.

CLASSICAL CORRECTNESS.

To the Editor of THE LANCET.

SIR,—I am glad that your reviewer, in his gratifying notice in your last issue of my "Index of Symptoms" agrees to the necessity for a word to express "reflexes" which have no connexion with the reflex arc; but I still prefer parergia to parergon. I have a great regard for classical correctness, and claim a large share in consigning to the lethal chamber that horrible mongrel uricacidæmia.

Parergia is formed on the same lines as synergia, and I am sure that had they felt a need for the word, the Greeks, who made *συνεργία* from *σύν* and *ἔργον*, would not have hesitated to make *παρεργία* from *παρά* and *ἔργον*.

I am, Sir, yours faithfully,

RALPH W. LEFTWICH.

Ebury-street, S.W., April 17th, 1915.

"UNPATRIOTIC DOCTORS."

To the Editor of THE LANCET.

SIR,—At the request of some of my clients who have seen a letter in the lay press, with this title, complaining of the lack of patriotism evinced by certain members of the profession, may I, as one with 40 years' experience in the engagement of locum-tenents for medical men, say a word in reply to the complaints. Before the war broke out the fees for substitutes were mostly 5 and 6 guineas, the increase in a great measure being due to the extra amount of work involved and the higher incomes earned owing to the Insurance Act. When the War broke out a large number of those who had been acting as locum-tenents at once offered their services and were accepted and given commissions at a remuneration of, roughly, 7 guineas a week, and consequently the fees paid to those remaining automatically went up to about the same figure, and at the present time a large number of men unable from one cause or another to serve their country abroad are doing so by taking duty at home for those who have gone on active service, and at moderate fees. Personally, I have not come across a single instance of 12 guineas being paid, and my register shows that out of a list of over 600 engagements that have passed through my hands during the last six months (mostly war ones) no fewer than 300 have been at 6 guineas, 235 at 7 guineas, 16 at 8 guineas, and the remainder at lower fees on hospitality terms, &c.

As regards the suggestion to invite those willing to help at reasonable rates of remuneration, I may say that early in the war through letters in the medical papers I invited all able and willing to help to communicate with me, and have met with a most loyal response from medical men up to 70 years of age who are doing their best in their country's need. Many of our allies are also helping, including Egyptians, Indians, Belgians, French, Russians, Japanese, and Greek.

I am, Sir, yours faithfully,

PERCIVAL TURNER.

Adam-street, Adelphi, W.C., April 19th, 1915.

MEDICAL INSPECTION OF SCHOOLS: ANNUAL REPORT OF THE MEDICAL OFFICER TO THE ABERDEEN SCHOOL BOARD.—In his fifth annual report Dr. George Rose, medical officer to the Aberdeen School Board, points out the significance of the coincidence of the advent and growth of picture palaces with an increase of scarlet fever and diphtheria cases. With regard to a recent outbreak of diphtheria, Dr. Rose states that neither the social position of the scholars, the site of the school, nor the ventilation nor method of heating had the slightest influence upon the disease. Among the children attending the public schools from 8000 to 10,000 have five or more teeth absent or decayed, and 27,000 are in need of dental treatment; and apart from the children dealt with at the dental clinic not over 1 per cent. probably will receive conservative dental treatment. Children fed on tea and bread are found to have the worst teeth, while the common statement that oatmeal feeders have worse teeth than others is at variance with the figures obtainable, which support the opposite view. Dr. Rose finds that tea is doing much harm among the young people. Extreme cases of tea-fed children can be picked out infallibly in the course of medical inspection. The lack of subcutaneous fat in the face, the faint lines running from the nose to the chin round the angles of the mouth, the half-frightened air, all tell, he says, of tea-poisoning, and form a type as patent to the skilled observer as is the alcoholic. Not many children suffer from lack of food, but in many cases the quality is unsatisfactory. Though most children are born healthy, there is a large infant mortality due largely to gastric disorders. This is followed in many of the survivors by rickets, the result of improper feeding. Most, if not all, of these disordered conditions are preventable.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

THE EXECUTIVE COMMITTEE.

A MEETING of the Executive Committee was held on April 15th, when the treasurer, Dr. Des Vœux, reported upon the financial position of the Fund, and presented the audited statement of accounts up to March 31st last given below.

Relief since March 31st has been granted in several directions, particulars of which were furnished, and clothes continue to be purchased in suitable cases, the outlay in this direction being carefully scrutinised by Mrs. Colebrook.

It will be remembered that at the meeting of the Executive Committee held on March 25th it was unanimously agreed to send a substantial sum to Belgium to meet the urgent needs of Belgian doctors and pharmacists remaining in their own country. This course was adopted after the committee had received detailed information as to the cases, and as to the machinery for distribution which had been adopted by the Aide et Protection aux Médecins et Pharmaciens Sinistrés. A representative of this body attended the meeting of the Executive Committee, showed by documents the way in which the information as to the individual instances had been compiled, and spoke from personal knowledge both of the extremely sad plight of many of our Belgian *confrères*, and of the efficacy of the methods adopted by pharmaceutical inspectors, both in medical and pharmaceutical cases, for testing the correctness of the sad stories. On hearing this gentleman's statement the committee decided to act without delay; hitherto it had not been possible to send money because there was no official body ready to receive it or to account to the committee for its employment. The sum of money was despatched immediately to Belgium. It was sent through the medium of certain banks and with the help of Mr. Herbert Hoover, the chairman of the National Relief Fund, and an eloquent letter of thanks has been received from Dr. Pechère, the chairman of the Aide et Protection aux Médecins et Pharmaciens Sinistrés. The Executive Committee propose to continue their large and definite scheme of expenditure, if the course is justified by reports received from Dr. Pechère's committee as to the employment of the money.

THE FUND AND THE WEST LONDON MEDICO-CHIRURGICAL SOCIETY.

It was decided by the West London Medico-Chirurgical Society some weeks ago to organise a reception in place of the annual dinner so as to enable the President to meet the members in a social manner during his year of office, and at the same time to afford the members an opportunity of contributing to the relief of their professional Belgian colleagues who are suffering so intensely in consequence of the war. A reception will accordingly be held at the West London Hospital to-night (Friday, April 23rd) at 8.30 P.M., when guests, including ladies, have been specially invited. The programme will include war exhibits, short addresses on war subjects (illustrated by lantern slides and pictures), music, and other entertainment. The charge for each ticket, whether for a member, a lady, or other guest, is 5*s*., and it is hoped that members will subscribe even if they are unable to be present. The whole of the proceeds, after the deduction of expenses, will be transmitted as a donation from the society to the Belgian Doctors' and Pharmacists' Relief Fund. Cheques may be made payable to either of the honorary secretaries, Mr. Oswald Addison, F.R.C.S. (125, Harley-street, W.), and Dr. Reginald Morton (66, Harley-street, W.).

THE WEEK'S SUBSCRIPTIONS.

The subscriptions received by Dr. Des Vœux up to Tuesday evening last, in addition to those previously acknowledged, and not including money collected by the Scottish and Irish Funds, are as follows:—

	£	*s.*	*d.*
Danish Union of Doctors (per Dr. Christopherson, Hon. Sec.) (third donation, total £290 5*s.* 8*d.*)—			
"Some Young Doctors from the State Hospital"	8	9	9
Dr. R. Ashleigh Glegg...	1	1	0
Lt.-Col. W. E. Scott-Moncrieff, I.M.S. ...	2	2	0
Dr. A. W. Hare	1	1	0
Mrs Howard, Maidenhead, collected by (per Dr. H. Macnaughton Jones)	8	8	0
Birmingham Local Committee (per Dr. R. Saundby, Hon. Sec.) (sixteenth donation, total £377 12*s.* 3*d.*)—			
Dr. J. Jameson Evans	2	2	0
Bournemouth Division, B.M.A. (per Dr. Eleanor C. Bond, Hon. Sec.) (second donation, total £109 12*s.* 6*d.*)—			
Mr. Frank Belben ...	3	3	0
Dr. W. H. Fawcett ...	2	2	0
Dr. F. Heasman	3	3	0

Subscriptions to the Fund should be sent to the treasurer of the Fund, Dr. H. A. Des Vœux, at 14, Buckingham-gate, London, S.W., and should be made payable to the Belgian Doctors' and Pharmacists' Relief Fund, crossed Lloyds Bank, Ltd.

THE APPEAL FOR SURGICAL INSTRUMENTS.

The Master of the Society of Apothecaries begs to acknowledge the receipt of surgical instruments kindly contributed by the following donors since the publication of the last list:—

Dr. H. W. Gardner, Shrewsbury; Mr. J. E. Burton, Middlewich, Cheshire; and Dr. A. G. Mackenzie, Shrewsbury.

Obituary.

SIR GERALD BOMFORD, K.C.I.E., M.D. LOND., L.R.C.P. LOND., M.R.C.S. ENG.,

LATE DIRECTOR-GENERAL, INDIAN MEDICAL SERVICE.

WE regret to announce the death of Surgeon-General Sir Gerald Bomford at St. Thomas's Home, London, on April 12th, at the age of 63. He was educated at King's College, London, and graduated as M.B. at the University of London in 1873. In 1874 he obtained the degree of M.D. and in the same year entered the Indian Medical Service, being appointed to the Medical College, Calcutta, first as resident surgeon and afterwards as resident physician and professor of pathology. In the two following years he served with the Perak Expedition, receiving the medal with clasp, and subsequently in 1886 was appointed professor of physiology at the Medical College, Calcutta, and later became its principal and occupied the chair of medicine. In 1905 he was appointed Director-General of the Indian Medical Service, which position he held till succeeded by Sir Charles Pardey Lukis some five years later.

Dr. N. I. Tirard writes: "The announcement of the death of Surgeon-General Sir Gerald Bomford will have been read with great regret by all who knew him. After he entered the army in 1874 he threw himself into his duties with characteristic energy and rarely revisited his old school. As a student he had a very distinguished position, and his fine presence always attracted attention. From early days he was devoted to his professional work, and, although he entered King's College in a year which produced many men who subsequently earned high honours, Gerald Bomford occupied a place in the foremost rank in all class competitions. He was awarded one of the junior scholarships at the end of his first year, and he gained prizes in anatomy and chemistry, and distinctions in several other subjects. In due course he became house physician and for a year before he entered the army he was Sambrooke medical registrar at King's College Hospital. This record of work, however, only exhibits one of the facets of a many sided character. He was one of the most regular supporters of the Medical Society of King's College, and was one of the honorary secretaries during the presidency of Professor William Rutherford, who then occupied the chair of physiology. At these meetings Gerald Bomford could always be counted upon for amusement, no matter what the subject of debate. Gifted with a sonorous voice, with easy fluency of diction, and with a somewhat deliberate delivery, he delighted his auditors with a masterful method of dealing with his opponents. His invective, often turned upon his best friends, never wounded; it served merely to enliven the meeting and to stimulate others to greater exertions. Junior members of the society might tremble, but the disputants went away together on the best of terms, and subsequently carried their friendship through the wards, to the army, and to India. In the steady industry of these early days, in the acquisition of ready speech, and in the understanding of his fellow men Gerald Bomford laid the foundations of his future success in the Indian army, and he left in this country many to rejoice when honours came to him, many to sorrow now that his career is ended."

WILLIAM SANDILANDS HARRISON, M.B., C.M. GLASG.,

LIEUTENANT-COLONEL, ROYAL ARMY MEDICAL CORPS.

LAST week we announced in our Service column the death of Lieutenant-Colonel W. S. Harrison, which took place on April 12th at Bankfield, Haslingden, the residence of his mother, at the age of 43 years. He graduated as M.B., C.M. at the University of Glasgow in 1893.

Colonel Sir W. B. Leishman, in a letter dated from the British Expeditionary Force, says: "By the death of Lieutenant-Colonel W. S. Harrison, the Royal Army Medical Corps has lost an officer whom it could ill spare and for whom, had he lived, high honours and distinctions would most certainly have been in store. There can have been no officer in the corps of his standing who was more universally respected and liked both for his exceptional professional qualifications and his sterling character. A sense of personal bereavement must be strong in all who knew him and read of his death. The writer had the privilege of the closest association with him as a fellow worker in the Royal Army Medical College for many years and was under a heavy obligation to him for loyal and untiring coöperation, both in research and in teaching, and the passing years served but to strengthen a feeling of admiration and respect for a character and intellect of exceptional strength. The research work accomplished by Lieutenant-Colonel Harrison in many lines is of great and permanent value, notably his important share in establishing typhoid inoculation upon a firm and scientific basis; the benefits resulting from this work are being reaped to-day by the army in France. His appointment to the chair of Tropical Medicine at the Royal Army Medical College proved an immense success and furnished an instance of that rare but admirable combination, a clinical observer of exceptional experience and insight, armed with a full practical knowledge of modern laboratory methods. The number of puzzling and difficult cases on which he was able to throw light and initiate a successful treatment must have been a reward in itself, but those who benefited by his skill, such as the writer and many another officer and man in the army, have good cause to keep his memory green. It was a hard stroke of fate which denied to him the chance of serving his country at this time, and one which he felt bitterly; but the fortitude and calm courage with which he endured his painful illness and faced the inevitable will not readily be forgotten by those whom he honoured with his friendship."

If we add nothing to Sir William Leishman's warm testimony to the character and attainments of his friend it is only because he has said so exactly what we should have desired to say. Colonel Harrison had already made himself a great name in tropical and preventive medicine, and has died before his qualities and merits were known much beyond his immediate sphere of work.

PANTLAND HICK, M.D. LOND., M.B., CH.B. LIVERP.,

HONORARY ASSISTANT PHYSICIAN, LIVERPOOL ROYAL INFIRMARY, ETC.

IN the death of Dr. Pantland Hick, which took place on April 17th, after a few days' illness, from a virulent attack of scarlet fever, the Liverpool Royal Infirmary mourns one of the most brilliant of its medical staff. Pantland Hick received his medical education at the University of Liverpool, when he graduated in 1904 as M.B., B.Ch., with second-class honours, after a distinguished student's career. He won the Lyon Jones scholarship, the Derby exhibition, and the Thelwall Thomas fellowship in surgical pathology. In 1906 he took the M.B., B.S., of the University of London, and in 1909 the M.D. of that University. Two years ago he was appointed honorary assistant physician to the Liverpool Royal Infirmary and subcurator to the pathological museum of the University of Liverpool, prior to which he was honorary physician to the Liverpool Stanley Hospital and assistant physician to the Liverpool Infirmary for Children. He was also a captain in the 1st Western General Hospital R.A.M.C.(T.F.). He was a most successful teacher in medicine at the Liverpool Royal Infirmary, where his clinic was highly prized by the students, with whom he was very popular. A career full of promise for the future has been thus sadly cut short at the early age of 34 years.

A medical correspondent, who was a friend of Dr. Pantland Hick for many years, writes:—

"By the death of Pantland Hick at a lamentably early age the profession in Liverpool is deprived of one of its most brilliant workers, and one whose great promise as a student had already shown the fruits of fulfilment. But great as is his loss to his professional colleagues, it will weigh still more heavily on his more intimate friends. He was as earnest and devoted in his friendship as he was to his work. The performance of his duties was marked by the most painstaking and conscientious qualities; he was ever ready to put his great knowledge and keen insight unreservedly at the disposal of his comrades, and the throng of students and post-graduates at his clinics testified to his ability and success as a teacher. His modest bearing, ready self-effacement, winning address, and sterling professional acquirements made him typical of the kind and gentle physician. Through all his work and scientific achievement there shone the simple, plain faith that is so often seen in the eyes of those we know as good and great. His loss will be deplored by all who knew him, not only as a capable and willing worker, but also as that of a kind, loyal, and honourable man."

WILLIAM THOMAS EDWARDS, M.D. LOND., F.R.C.S. ENG., LL.D., J.P.,

CONSULTING PHYSICIAN TO THE CARDIFF INFIRMARY.

Dr. W. T. Edwards, who died from bronchitis at Cardiff on April 11th, at the age of 93, was one of its most distinguished citizens and a great benefactor to the city, his donations to University College, Cardiff, amounting in all to some £3000.

Dr. Edwards, who was the son of a medical man, was born at Caerphilly on Dec. 6th, 1821. He was the great-grandson of William Edwards, who in the middle of the eighteenth century spanned the Taff at Pontypridd with the largest one-span stone bridge in the world, gaining thereby a European reputation as a bridge-builder. Edwards received his medical education at University College, London. He became a Member of the Royal College of Surgeons of England in 1842 and Fellow in 1879, and took the Licence of the Apothecaries' Hall in 1843. In 1844 he graduated as M.B. at London University, gaining the gold medals in anatomy and physiology, in materia medica and in midwifery. In 1850 he proceeded to the M.D. degree. A life governorship was conferred on him by University College, London, in 1871.

In 1852 Dr. Edwards began that active connexion with the Cardiff Infirmary which lasted until he was appointed on the consulting staff. He was in succession surgeon, consulting surgeon, physician, and consulting physician. In 1902 his jubilee of service at the infirmary was celebrated at a banquet given by his local *confrères*. In 1885 he was President of the British Medical Association on the occasion of its holding its annual meeting at Cardiff.

Dr. Edwards's activities were by no means confined to things relating to his own profession, for municipal and religious movements will enshrine his name in their records as an active and efficient worker. His funeral, which took place on April 15th, showed by its thronged attendance and representative character the general esteem in which he was held.

DEATH OF DR. WALTER LEWIS THOMSON, OF DERBY.—Dr. Thomson died recently at the early age of 40, it is supposed from infection contracted by inhalation in the course of his duty. Dr. Thomson, who was instrumental in solving the mystery of the pork-pie outbreak at Chesterfield a few years ago, was senior assistant medical officer of health and school medical officer for Derbyshire, and was in charge of the county tuberculosis dispensary. He received his medical education at Glasgow University and Cardiff, and graduated as M.B., Ch.B. in 1897, and M.D. (with commendation) in 1904. He took the D.P.H. Cantab. in 1902. He was formerly assistant medical officer of health for Lanarkshire and physician-superintendent of the Fever Hospital, Motherwell.

DEATH OF DR. JAMES HUXTABLE BENDLE, OF BATH.—Dr. Bendle, who was county oculist for Somerset, died with painful suddenness from hæmorrhage at Bath on April 13th. He studied medicine at St. Mary's Hospital, and took the joint qualification of the London Board and the M.B. Lond. in 1898. He was formerly resident medical officer at York Dispensary, and assistant house surgeon, and afterwards house surgeon, at the County Hospital, York. He practised for some seven years at Abbots Bromley, Staffordshire, until his health broke down. Dr. Bendle leaves a widow and two children.

The War.

THE CASUALTY LIST.

Lieutenant M. Burnett, R.A.M.C., is reported killed during the operations in the Persian Gulf. He was formerly house physician at St. George's Hospital, and had been for three years in the Royal Army Medical Corps.

Lieutenant E. Stratford, R.A.M.C., who was attached to No. 8 British Field Ambulance with the Lahore Division of the Indian Expeditionary Force, has died in England from shell wound received at Neuve Chapelle.

Captain E. B. Allnutt is reported wounded during the operations in the Persian Gulf.

THE MEDICAL HISTORY OF THE WAR.

A committee, under the presidency of the Director-General, Army Medical Service, has been formed to provide the necessary coördinating authority for the compilation of an adequate medical history of the war.

In connexion with each of the chief subdivisions of the work, military and civilian members have been appointed, except in the case of the Section of Hygiene, where both members are military.

The constitution of the committee under the presidency of the Director-General is as follows:—

Medicine.

Lieutenant-Colonel O. L. Robinson, R.A.M.C., and Professor Sir William Osler, Bart., M.D., F.R.S.

Surgery.

Lieutenant-Colonel E. M. Pilcher, D.S.O., M.B., F.R.C.S., R.A.M.C., and Colonel F. F. Burghard, M.D., M.S., F.R.C.S.

Pathology and Bacteriology.

Colonel Sir William Leishman, C.B., M.B., F.R.C.P., F.R.S., and Captain F. W. Andrewes, M.D., F.R.S.

Statistics.

Lieutenant-Colonel H. P. W. Barrow, R.A.M.C., John Brownlee, M.D., D.Sc., and Lieutenant-Colonel W. N. Barron, M.V.O., R.A.M.C.

Hygiene and Sanitation.

Colonel W. H. Horrocks, M.B., K.H.S., and Lieutenant-Colonel W. W. O. Beveridge, D.S.O., M.B., R.A.M.C.

Historical and Secretarial.

Captain F. S. Brereton, R.A.M.C., and W. M. Fletcher, M.D., Sc.D., F.R.S.

In each section the members of the committee have been given authority to co-opt for the purposes of the section other persons, and it is hoped that in the various sections the best results of the varied experience now being gained will be selected and arranged for publication in the Medical History, and not left to be distributed in scattered communications published independently by individual observers.

SIDE-LIGHTS ON MILITARY MEDICINE.

An indirect and more or less unforeseen result of the wholesale militarisation that is in progress is the unprecedented opportunity it affords, incidentally, for a sort of medical census of the male population, especially efficient in countries where conscription is in force since this means that virtually the whole male population of the country is medically reviewed and is, in addition, subjected to a series of crucial traumatic and psychical tests. Where conscription runs we have, in times of war, a preliminary examination of those called up for service which enables us to ascertain exactly what proportion of males between 18 and perhaps 50 years of age suffer from the various disabling diseases and infirmities comprised in our nosology—statistical elements not procurable in any other way. Of even greater interest is the information that warfare affords concerning the vulnerability to disease of the fighting elements and the degree of protection provided by sanitary measures, including vaccination and seropathically induced immunity. Already we have learned much. The subjects of heart disease, for instance, are shown to be capable of vastly more resistance to fatigue and exposure than we should *a priori* have expected,[1] though no doubt to the detriment of their subsequent prospect of life. Dr. Legueu in the *Journal des Praticiens* of March 20th, 1915, writes an interesting article on the prevalence of urinary incontinence and vesical neuroses among the combatants, a wholly unexpected manifestation of nervous commotion. But most interesting of all perhaps are the remarkable effects of cerebral commotion, apart from physical injury, induced by high explosives. Fine robust men, excellent experienced soldiers, are found to break down under the terrible stress of a heavy bombardment and develop neurasthenia, melancholia, or traumatic hysteria.[2] In some the hebetude and melancholic taciturnity only last for a few days and disappear when the subject is set to some manual work that distracts his attention, but in others it is of a more permanent character. Cases are on record of more or less prolonged amnesia associated with curious disturbances of the functions of speech and vision. One man, for instance, could not pronounce familiar words, though he could spell them, and though he understood them when spelled he failed to grasp their meaning when pronounced. The intellectual status of the victims puts simulation out of the question, the troubles being far too complicated and consistent for a layman to reproduce for weeks at a time. In a somewhat different category are cases in which a trifling skin wound has induced functional paralysis of adjacent muscles or even of one side of the body, only to be cured by "suggestion" in one form or another, and in this direction high-frequency currents, by virtue of their awe-inspiring phenomena, have proved singularly successful among French troops. The tremendous strain thrown on the nervous system by prolonged exposure to the hardships of life in the trenches and heavy shell fire starts into being any latent tendency to somnambulism, and some extremely thrilling tales are told of the aberrations observed during the first few nights following a heavy fight. Cases of downright insanity have been extremely rare, at any rate among the French troops, in fact, so far, not one has been placed on record. To useful work which the medical returns of the war are opening up for statisticians imagination can hardly set bounds. It is of the utmost importance therefore that these returns should be well kept.

SOLDIERS' AND SAILORS' INSURANCE.

The Insurance Commissioners have recently issued a reminder (Leaflet No. 29, Revised) as to the benefits to which seamen, mariners, and soldiers are entitled under the Insurance Acts. They have also sent letters to the clerks of Insurance Committees (Circular 53/I.C.) giving information as to a scheme for dealing with soldiers discharged from the army suffering from tuberculosis, the same arrangements applying, if occasion arises, to seamen or mariners belonging to Approved Societies. The matter is dealt with in connexion with the demand for hospital space for other purposes and in order to provide for the taking over of tuberculous soldiers as promptly as possible by Insurance Committees when they need continued residential treatment. As committees may not have beds ready when wanted, and as it will not be possible to postpone the date of the soldiers' discharge from the military hospitals, the Commissioners will coöperate by taking beds in private institutions in which the soldiers in question will be placed temporarily, pending preparations for their reception by the appropriate committees. In respect of these cases a sum will be available to the committee out of the Central Sanatorium Benefit Fund under Article 24 of the Payments to Insurance Committees Regulations, 1914, and payments thus made to committees will be supplemented by the Commissioners by grants out of the Grant-in-Aid of £100,000, provided by Parliament on the Supplementary Estimates 1914–1915, the effect being that committees will be credited with a possible sum of £20 for each case taken over by them, deduction being made to meet the expense of the temporary provision referred to. The circular makes recommendations and gives full particulars of the procedure which will be adopted when cases of soldiers suffering from tuberculosis and needing continued institutional treatment arise. It explains that the basis of the proposed grants has been framed with reference to the fact that the cases in respect of which they are payable have all been certified by the military authorities to require some period of residential treatment.

GERMAN MEDICAL PAPERS.

Further contributions to German papers have reached us which show that the medical problems of the war are being carefully considered. Of typhus fever we learn the following:—

> Typhus exanthematicus, although almost confined as yet to the prisoners' (Russian) camps and those who have had to do with them, has taken heavy toll of distinguished men, of whom Professor Cornet, author of a standard German work on tuberculosis, is the latest victim. Among the Russian prisoners themselves the disease appears to be but slightly fatal, Dr. Lindner (Linz) recording no death among 300 cases in a camp of 9000 persons, while 24 per cent. of infected attendants in the same camp succumbed. In Tsingtau figures had previously been given by Fürth as follows: Mortality among Europeans 25 per cent., among the Chinese themselves 11 per cent. only; in accordance with Römer's law, the smaller the distribution of an infection among a population the greater the case mortality. No suggestions for treatment are at present forthcoming, and the diagnosis may be very difficult. Professor Klemperer and Professor Zinn, who attended Professor Jochmann, who also has died of this fatal disease, state that he had irregular fever, headache, and sleeplessness ten days after visiting cases. A septic throat followed, with bronchitis and heart weakness, and on the sixth day a transient roseola on the chest and abdomen. The spleen was enlarged to percussion, but a Widal reaction was negative, and the blood contained no typhoid bacilli. The roseola returned on the ninth day and became petechial. Death occurred on the eleventh day from heart failure. Special attention is due to the fact that of the three physicians in attendance and of the other seven persons, nurses and family, in close attendance on the patient, not one became infected. Jochmann himself was entirely convinced that a perfectly clean patient is no danger to his surroundings, and records in his book the observation of a Serbian doctor who placed other patients in the same bed with a washed typhus patient clad in clean linen without any of them taking the infection.
>
> It is becoming increasingly certain that lice are the sole carriers of the virus from patient to patient, and it was another victim of the disease, Professor v. Prowazek, of Hamburg, who showed that a single louse from an infected patient could convey infection to an ape. On the other hand, Curschmann says that infection can be conveyed by straw, clothes, &c., months old when all the lice and nits must long have died out; but in this case the explanation is advanced that the virus has a certain tenacity, possibly a resting form, which is, as such, not infectious for us but only for the louse, which takes the virus up and activates it, acting to some extent as a sensibilisator—conveying it then to man by its bite. The association of the louse with typhus is no new idea, but was described by the Hungarian (typhus has been known for centuries as the "Hungarian disease"), Tobias Coberus, at the beginning of the seventeenth century, who thought the louse had a psychic effect upon the human subject and who recommended garlic externally for prophylaxis, others at that time using marjoram, mint, cloves, and other ethereal oils for the same purpose. Of more modern remedies, Professor Blaschko, as an alternative to naphthalene where the smell is objected to, suggests mercury as the only effective alternative, preferably in the form of hydr. c. cret. (1 : 4), carried to the amount of 30 grm. in a bag in each trouser pocket. Professor Sigmund Fränkel, whilst experimenting with oil of anise, was accidentally supplied with anisol, which is phenyl-methyl-ether, and this proved to be from six to eight times more poisonous to lice than any other remedy, being at the same time one-twelfth as poisonous to man as phenol, and causing no eczema or irritation of the skin. The only analogy he could find was di-methyl-resorcin, a single drop of which under a bell jar kills frogs in three to five minutes. On a large scale the Bavarian Home Office recommends the employment of SO_2 as a disinfectant, best prepared by burning a mixture of CS_2 90 per cent., water 5 per cent., and methylated spirit 5 per cent., 2½ kilos for every hundred cubic metres of room space. For prophylaxis the attendants should closely fit their garments at the wrist and ankle, and use strongly smelling ethereal oils or naphthalene, bearing in mind, further, that in the experience of Professor Kraus, of Buenos Aires, infection may be avoided by thorough ventilation.

THE BRITISH RED CROSS SOCIETY.—The fourth annual report (1914) of the County of London Branch of the British Red Cross Society (founded Dec. 9th, 1909) shows that on the outbreak of war all divisional secretaries returned at once from holiday leave. Large numbers of enrolments took place, and Colonel Gimlette's scheme of registering promised articles for the equipment of auxiliary hospitals was at once put into action, and serving centres were established all over London. The War Refugees' Committee was rendered aid in housing, and the following homes and hospitals were accepted by the society: Weir Hospital, Balham, 50 beds; Hospital for Officers, 24, Park-street, 19 beds; 9, Cedars-road, Clapham Common, 36 beds; 78, Onslow-gardens, 25 beds; Cedar Lawn Hospital, 36–42 beds; Oakhurst, Erith, 20 beds; Territorial Hospital, White City, 40 beds. Eight detachments were mobilised, of which one has since been demobilised. By means of boxes large sums were collected. A member is selected from each of the detachments for service as women orderlies at the King George Hospital, Mrs. Scott Gatty, commandant of No. 50, being in charge. A useful work is the systematic inquiry made among the London hospitals for missing officers and men. The present strength of the branch comprises 70 detachments with a total of 2711 all trained to work. Each of the divisions corresponds with the area of one or more metropolitan boroughs—viz., St. Marylebone, Greenwich and Woolwich, Camberwell, Hammersmith, Hampstead, West Hampstead, Islington, City of

Westminster, Kensington, Chelsea, Battersea, St. Pancras, Paddington, Hackney and Stoke Newington, Lambeth, Putney and Fulham. To these Poplar has lately been added. All report good work done. The finances of the branch were fortunately put on a more satisfactory footing early in 1914, so that in place of a deficit, as always formerly appeared, the branch had a balance in hand at the end of the year amounting to upwards of £374.

The East Lancashire branch of the British Red Cross Society has undertaken the whole of the work in connexion with the transport of wounded soldiers, British or Belgian, sent to Manchester for treatment. This involves the meeting of hospital trains, usually during the night, and the subsequent transfer of patients to and from the many military and Red Cross hospitals in this area. Since the outbreak of the war this transport section has met 84 trains and transported 12,306 sick and wounded soldiers to hospital. In addition many wounded have been conveyed from one hospital to another, which brings up the total number of transports carried by this society to about 20,000.

Lieutenant-Colonel Sir Courtauld Thomson has been appointed, with the approval of the Admiralty and the War Office, head of a commission to be sent to Malta and the East by the Joint War Committee of the British Red Cross Society and the Order of St. John, and will shortly proceed to the Mediterranean.

VACANCIES FOR MEDICAL OFFICERS.—We are asked to state that there are vacancies for five medical officers prepared to serve abroad in the 2nd and 3rd Line Welsh Border Mounted Brigade Field Ambulance. Pay and allowances as in the Regular Army, together with outfit and camp kit grants. Full particulars can be obtained on application to Major D. C. Leyland Orton, Officer Commanding, Thomas-street, Chester.

UNIVERSITY OF ABERDEEN AND THE WAR.—At the spring graduation at the University of Aberdeen many of those graduating were in khaki and several of the professors wore the uniform of the Royal Army Medical Corps. Owing to the large number serving with the colours the number of undergraduates present was much smaller than usual. The Principal, in his address, stated that over 1100 graduates, alumni, and students were serving with the forces, of whom some 150 were actually under fire at the time of speaking. With regard to medical students, Principal Smith said that on service or under training in the Officers' Training Corps there were 368 students, or rather more than 50 per cent. of the whole. Of the rest a certain number were under age, some applied for commissions or sought to enlist, and some had not the necessary physical qualifications. The executive of the General Medical Council and the present heads of the Military Department of the War Office had strongly advised many medical students to complete their curriculum in view of the needs, both civil and military, in the immediate future. The Principal also read the roll of dead, seven in number, which included the names of Dr. Thomas Peppé Fraser, Colonial Medical Service; Surgeon William Mellis Mearns, R.N.; Lieutenant-Colonel W. H. Gray, I.M.S.; and Lieutenant Angus Forsyth Legge, Medical Company, Singapore Volunteer Corps.

LICE IN THE TRENCHES.—We are asked to state that on Tuesday afternoon, April 27th, between the hours of 3 and 5, Mr. M. E. MacGregor will give a demonstration at the Wellcome Bureau of Scientific Research, 10, Henrietta-street, Cavendish-square, W., on Lice and their Prevention, to which all interested are invited. The subject is one which, while of paramount importance at the present juncture in relation to the war, occupies an important place also in regard to civil life, and a good attendance may therefore be reasonably expected, including many general practitioners. It should be of particular interest to those practising in the densely populated areas.

INDIAN WARD OF THE ST. JOHN AMBULANCE HOSPITAL BRIGADE.—Her Highness the Mahendra Maharani Sahiba of Panna has made a donation of Rs.1000 to the Indian Ward of the St. John Ambulance Brigade Hospital now being organised on behalf of the Indian Council by the Order of St. John of Jerusalem. This amount is included in a contribution of Rs. 5000 to the St. John Ambulance Red Cross War Fund, the fifth contribution sent by Mrs. Spence, wife of the Political Agent at Nowgong, Bundelkhand. Major Perry, I.M.S., commanding an Indian Stationary Hospital, says that the St. John Red Cross gifts were exceedingly useful and much appreciated. Ahmed Saneh Pasha, an Arab notable of Basra, has contributed Rs.1500 to the St. John Ambulance Association in India to assist the work carried on by that society on behalf of the wounded, a striking proof of local Arab sympathy with the British cause.

ROYAL HOSPITAL FOR SICK CHILDREN, ABERDEEN.—This hospital suffered on the outbreak of war from the mobilisation of most of the members of the medical and surgical staff, and the lady superintendent was also called up for duty. The directors made the best arrangements possible under the circumstances, and by the willing and efficient coöperation of the reduced staff, and the assistance of others, they believe that the work has been efficiently overtaken. Owing to the very exposed position of the hospital, in the event of the bombardment of the city, the directors felt that the inmates should, if possible, be removed to a safer place. The trustees of the late Mr. Thomas Ogilvie generously offered the use (rent free) of Kepplestone House, Rubislaw, where the patients were removed some time ago, since when out-patients have, owing to facilities granted by the board, been treated at the Aberdeen Royal Infirmary.

WOUNDED ALLIES RELIEF COMMITTEE.—We are informed that the Wounded Allies Relief Committee has recently extended its good work in supplying Belgian *réformés* soldiers with artificial limbs. A number of cripples are now assembled at the committee's No. 2 Home for Disabled Belgian Soldiers (45, Courtfield-gardens) for this purpose, and many have already been examined by Sir William Collins, K.C.V.O. Food for this home has been promised by the National Food Reform Association, while Dr. Bridges is acting as honorary medical adviser, and Mr. C. St. Aubyn-Farrer is giving massage and electrical treatment. Gifts of clothing and of French and Flemish books will be gratefully received by Miss Humby, matron at the home. A very successful branch of the committee's work is the training home at Pontefract, where many thousand men are under care and supervision. Queen Alexandra recently wrote to the committee thanking them for the trouble they had taken in guiding one particular case to a successful issue. The committee have been advised by telegram that the advance party of its typhoid hospital unit recently sent to Serbia has arrived at Nish, and, at the request of the Serbian Government, is proceeding to Kragujevac, where the hospital, consisting of 100 beds, will be established. Ten other nurses, under the charge of Miss Edith Mackenzie, house sister of the City Fever Hospital, Birmingham, will shortly follow. All communications for the committee should be addressed to Mr. Albert Van der Velde, honorary hospital superintendent, Sardinia House, Kingsway.

THE OPEN-AIR TREATMENT OF TYPHUS FEVER.—Sir Clifford Allbutt, in a letter to *The Times* of April 15th, refers to his experience during the Leeds outbreak of typhus fever during the "sixties," of which the mortality was very heavy. In consequence of a remark of the late Professor Rolleston, of Oxford, concerning the "Irish fever," that "not a few of the patients carried out into the hedge bottoms as moribund, nevertheless recovered," he was led to test open-air treatment as a principle of cure. He had the staff warmly clad and all the windows taken out or screwed firmly open. The mortality of all cases fell promptly from 16–17 per cent. to 6–7 per cent., and the infective activity was much reduced. He therefore strongly urges that in Serbia every typhus fever patient should be carried out into the open air, in we weather with a waterproof coverlid for sufficient protection, and that every attendant should wear glazed cotton overalls and protect the neck and hair in like manner.

SOCIETY OF MEDICAL OFFICERS OF HEALTH: SCHOOL MEDICAL SERVICE GROUP.—A meeting of this group was held at the society's offices, 1, Upper Montague-street, Russell-square, W.C., on April 10th. The financial position of the past year was considered and officers were appointed. The reply of the council of the parent society to the petition of the group for the formation of a school medical service branch was considered and a resolution was passed with the object of improving the representation of the group on the council. The recent statement of Sir Alfred Keogh, Director-General, Army Medical Services, War Office, and the circular of the Board of Education as to the urgent need for more medical officers,[1] were considered, and it was unanimously resolved :—

> That the School Medical Service Group notices the grave appeal issued by the War Office for more medical officers, and urges members of the School Medical Service to respond to this appeal.

Members of the service having any difficulty in obtaining leave of absence or a substitute should apply to the honorary secretary of the group (Dr. A. Ashkenny, 2, London-road, Basingstoke). A joint paper by Dr. C. W. Hutt and Mr. G. Finch was read on School Medical Service Work and the British Army, pointing out the relation of such work to the physique of the army.

SHOP ASSISTANTS AS SOLDIERS.—The Early Closing Association is the oldest trade institution in the country, and has been supported by both employers and employed in its efforts to solve the vexed question of hours of labour. The board of management are anxious to maintain the best traditions of the association's past history by recognising in a practical manner the response of shop assistants to the call of the war. The patriotism of those shopkeepers who have encouraged their men to enlist, and who in many cases are looking after the dependents during the absence of the breadwinner, deserves the gratitude of the country. The authorities of the association suggest that the most practical way of showing this would be to improve the conditions of labour in shops, pending legislative protection, ere the men return to civil work. When victory has been gained the country will need, more than ever, a strong and hardy race to uphold national prestige, and this cannot be secured by working young men and women in shops until undue hours. The association will assist soldiers to obtain employment after the war is over, and a register is being prepared of those who propose to return to shop life. Captain Albert Larking, secretary of the Early Closing Association (3, Tudor-street, London, E.C.), will be glad to hear from shop assistants now on active service, whether at home or abroad, as to their intentions in this direction.

THE SAMARITAN HOSPITAL, BELFAST.—At the annual meeting of this hospital held on April 12th it was reported that the matron (a sister under the Territorial Branch) was called up for war service in August last, and as a result the committee decided to close the hospital, and since Jan. 1st, 1915, it has been given over to the Ulster Volunteer Hospital as an annexe for wounded soldiers.

THE King and Queen have promised to attend Madame Clara Butt's subscription concert to be given at the Albert Hall on May 13th in aid of the British Red Cross and the Order of St. John. Mr. Kennerley Rumford, who has been serving with the Red Cross Society since the war started, has promised to take part. The expenses are being met by Madame Clara Butt.

THE Derbyshire County Council have decided to offer to the War Office the services of their entire medical and nursing staff for administering a hospital of 300 beds, provided the Local Government Board will sanction the temporary use of the new tuberculosis sanatorium at Chesterfield, which cannot be staffed at present through the scarcity of medical men.

THE War Office announces that the establishment of military hospitals on a large scale for convalescents as well as for the sick and wounded will preclude the necessity for accepting further offers of private houses for these purposes.

A MOTOR ambulance, to be known as the City of London Russian Cavalry Ambulance, has been presented by Mr. Walter Winans to the Russian Red Cross Society.

ACCORDING to a German wireless from Berlin, dated April 15th, the Emperor has decorated Professor Roentgen with the Iron Cross on the occasion of his 70th birthday, thus acknowledging his eminent services to surgery.

Medical News.

WARREN TRIENNIAL PRIZE.—The Warren triennial prize, which was founded by the late Dr. Jason M. Warren in memory of his father, is awarded to the best dissertation on some subject in physiology, surgery, or pathological anatomy, the arbitrators being the physicians and surgeons of the Massachusetts General Hospital. The subject for competition for the year 1916 is on some special subject in physiology, surgery, or pathology, and the dissertation must be in either English, French, or German, typewritten, and suitably bound. Work that has been published previously will not be considered in competition. The name of the writer must be enclosed in a sealed envelope, on which must be written a motto corresponding with one on the accompanying dissertation. Any clue given by the dissertation, or any action on the part of the writer which reveals his name before the award of the prize, will disqualify him from receiving the same. The amount of the prize for the year 1916 will be $500. Dissertations will be received until April 14th, 1916. A high value will be placed on original work.

THE LATE JAMES BANNERMAN CUNNINGHAM, M.B., C.M. EDIN.—Dr. Cunningham died on April 4th at Ruyton, Salop, after a very brief illness from septicæmia, at the age of 62. He entered the profession in the late "seventies," and was at first in practice at Prestonpans, East Lothian. Subsequently, after a short sojourn in Canada, he practised at Tongue, Sutherlandshire, and finally at Ruyton, where he spent the last 23 years of his life. Dr. Cunningham was a man of robust health, was keenly addicted to outdoor pursuits, but was ever conscientious in the discharge of duties. He was very popular among the working classes, with whom he had a happy manner; though sometimes brusque and given to plain speaking if occasion arose, he possessed a natural kindliness and sincerity which found him many friends wherever he went. He leaves a widow and ten children, most of whom are grown up. The funeral was largely attended.

THE MENTAL AFTER-CARE ASSOCIATION.—This association, which is the only charity of its kind in the United Kingdom, assists poor persons convalescent or recovered from institutions for the insane from all parts of the country, and the report of the council for the year 1914 shows a record of much good work. During 1914 applications on behalf of 373 persons were received, of whom 225 were women and 148 men. This, however, does not represent all the cases dealt with in the year under notice, as nearly 200 old cases also received attention. As a result of the war greater calls upon the services of the association may be expected, and the charitable public will no doubt see that the really useful work which is done by this charity is not hampered by lack of financial support.

NORTH STAFFORDSHIRE MEDICAL SOCIETY.—The first meeting of this new society took place on March 25th, at the North Staffordshire Infirmary, when cases and specimens were exhibited. The following are the officers of the society :—President: Dr. John Russell. Vice-President: Dr. F. Shufflebotham. Treasurer: Mr. Jonathan Steele. Secretaries: Mr. R. H. Dickson and Mr. E. E. Young. Members of council: Dr. C. F. Daly, Dr. T. Basil Rhodes, and Dr. W. Mitchell Smith. The meetings are announced to take place monthly, except July, August, and September.

ERRATUM.—In the pass-list of the University of London (Second Examination, Part II.), published in THE LANCET of April 10th, p. 780, the † and ‡ (indicating distinction in anatomy and pharmacology) were unfortunately overlooked in the case of Emily Catherine Lewis, and the ‡ (distinction in pharmacology) from the names of Bruce Maclean and Benjamin Thomas.

ACCORDING to an official memorandum, it is expected that the inquiry undertaken by the Royal Commission on Venereal Diseases will extend at least until the end of March, 1916.

---

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

The Parliamentary Session.

PARLIAMENT resumed its sittings on Wednesday, April 14th. Business is mainly confined to matters connected with the war. For the meantime sittings will be only upon Tuesdays, Wednesdays, and Thursdays, but special arrangements are being made to expedite the procedure relating to the notice required for questions to Ministers. Although these will be concentrated into three days a week, it does not follow that they will be less numerous in the aggregate than they would be had the House sat on the normal occasions.

Antityphoid Inoculation.

Mr. TENNANT, the Under Secretary for War, again states that he is not in a position to announce any change of policy with reference to the inoculation against typhoid fever of officers and men in the army.

Several questions have been asked within the past week in the House of Commons which are framed so as to suggest a desire to discredit inoculation, but in every case they have elicited nothing from the representative of the Government to show any intention to depart from the present policy.

The late Dr. John Esmonde, M.P.

Dr. JOHN ESMONDE, whose death is announced, was one of the few medical members of the House of Commons. He sat for several years as one of the Nationalist members, and was popular in all parts of the House. During the controversies connected with the passing of the National Insurance Act he took a close interest in the conduct of the negotiations concerning the position of the medical profession. He was a few months ago gazetted a captain in the Royal Army Medical Corps, and took a very active part in recruiting for the various branches of the naval and military services.

Mental Treatment Bill.

Mr. CECIL HARMSWORTH, the Under Secretary for Home Affairs, has introduced a Bill in the House of Commons "to facilitate the early treatment of mental disorder of recent origin arising from wounds, shock, and other causes." It was read a first time.

The House of Commons and Alcoholic Liquors.

In the House of Commons on Tuesday, April 20th, a motion was moved expressing the opinion that during the continuance of the war no alcoholic liquors should be sold in the refreshment-rooms or at the bars attached to the House. The debate showed the existence of a considerable amount of divergent opinion, and for that reason it was adjourned. But it has to be added that the amount of alcoholic liquors consumed at the House is now surprisingly low. It is stated that the total liquor bill for the two days on which the House sat last week was only 4*s*. Meantime no declaration has been made to the House of the policy which the Government will propose to pursue in the country with reference to the problem of drink as it affects the output of munitions of war.

The Finance of the National Insurance Act.

Some decreases in the sums which have to be found by Parliament for financing the operations of the National Insurance Act are noted in civil service estimates for 1915–16. There is a fall of £600,689 on the vote for the National Health Insurance Joint Committee. The large reduction of £350,000 on subhead relating to sickness benefit (women) is partly due to the fact that in the Supplementary Vote taken in July, 1914, provision was made for two years, and partly to the fact that, as the subhead was then put in the form of a grant-in-aid, an unspent balance can be applied in diminution of the requirements for 1915–16. There is a decrease of £95,000 on the vote for the treatment of tuberculosis (special grants), it being anticipated that the sum of £385,000 will be sufficient to provide all grants which will be earned. The sum voted for pathological laboratories in July, 1914, has not been spent, and a reduced provision of £25,000 has been included for 1915–16.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 14TH.

Cerebro-spinal Fever.

Sir J. D. REES asked the Parliamentary Secretary to the Local Government Board whether local bodies had been warned of the necessity for dealing with overcrowding, want of ventilation, and uncleanliness in areas surrounding London, in view of the existence and possible spread of spotted fever and of the recent report thereon of Dr. A. Newsholme,[1] medical officer to the Local Government Board; and, if not, whether he would now issue a warning letter.—Mr. HERBERT LEWIS replied: Dr. Newsholme's recent Memorandum on cerebro-spinal fever was sent on Feb. 22nd to the sanitary authorities of all districts in England and Wales, with a circular in which the Local Government Board say that they trust that the council and the medical officer of health will take such steps as may be necessary on the lines indicated in the Memorandum should any case of the disease occur in their district. The Memorandum states that in view of the well-known association of cerebro-spinal fever with overcrowding, insufficient ventilation, and uncleanliness, the avoidance of these conditions becomes a matter of prime importance. A copy of the circular and the Memorandum was also sent to each medical officer of health.

Medical Men as Prisoners of War.

Lord ROBERT CECIL asked the Under Secretary for Foreign Affairs whether there were still any British medical men held as prisoners of war by the Germans; if so, how many and what steps the Government proposed to take in order to procure their release.—Mr. PRIMROSE replied: It is believed that there are only three British subjects who claim to be entitled to release as medical men now detained in Germany. Representations on their behalf have been made through the United States Ambassador. According to the latest information the number of military doctors still detained in Germany is 50. Of these, 35 have been officially reported as prisoners through the United States Ambassador and 15 unofficially. The White Paper shows what steps have been taken to obtain the release of these prisoners.

Lord ROBERT CECIL: Is it a fact that prisoners in hospital in Germany, either as patients or doctors, are not allowed to write to their relatives freely; and, if so, what are the reasons for this treatment?—Mr. PRIMROSE: I have no information to show that doctors in hospital are treated differently from other prisoners of war in the matter of correspondence. Inquiries are being made through the United States Ambassador on this point.

Lord ROBERT CECIL: Is the honourable gentleman not aware that a particular doctor who has to attend British prisoners in a certain hospital has through the commandant of the hospital informed his wife that he is not allowed to write?—Mr. PRIMROSE: I will make inquiries about that. I have not heard of it.

THURSDAY, APRIL 15TH.

War Casualties.

Replying to Mr. HOGGE, Mr. TENNANT, Under Secretary for War, stated that the total of British casualties in the war up to April 11th inclusive was 139,347.

Certifying Sickness in Ireland.

Mr. GINNELL asked the Chancellor of the Duchy of Lancaster to say on what scale doctors were paid for certifying sickness under the National Insurance Act in England; what sum that was estimated to amount to annually; what the payments for this service amounted to annually; the Irish branch of the British Medical Association having consented to accept that scale of payment, would he say why it had not been paid; what independent medical approval, if any, the Irish Insurance Commissioners had for the treatment of the sick which their different system of certification involved; and, seeing that out of £97,100, Ireland's equivalent for this purpose, only £44,000 were spent on it, would he say whether the balance of £53,100 went into the Irish National Health Insurance Fund or was wholly lost to Ireland.—Mr. MONTAGU answered: There is no separate payment for the provision of certificates of incapacity for work under the National Insurance Act in England. The Exchequer grant of 2*s*. 6*d*. per insured person (equal to about £1,300,000) is a grant-in-aid of medical benefit generally, and this grant secures not only the provision of certificates but also other services in connexion with medical treatment and attendance. Any such comparison as that suggested by the honourable Member is, therefore, misleading. As regards the fourth and fifth part of the question I would refer the honourable Member to the full reply which I gave to similar questions on March 3rd.[2]

Convalescent Sailors and Soldiers.

Lord ROBERT CECIL asked the Under Secretary for War what steps the Government were taking to secure the restoration to health of convalescent sailors and soldiers discharged from hospital on sick leave, and what provision was made for soldiers and sailors invalided out of the service in consequence of illness resultant from active service.—Mr. TENNANT said in reply: Soldiers on discharge from hospital are as far as possible sent to convalescent hospitals or homes. Sick furlough limited to one week is only given in cases where the men are ready for duty or light duty. Soldiers requiring medical aid while on furlough may apply for it to the nearest military station or, in cases of emergency or if residing at a distance from a military hospital, to a civil practitioner. The new scale which will be adopted as a result of the recommendation of the Select Committee is under consideration. The question of allowing further hospital treatment for discharged soldiers who have been granted disability pensions is under consideration.

---

[1] THE LANCET, Feb. 27th, 1915, p. 452.

[2] THE LANCET, March 13th, 1915, p. 576.

Tuesday, April 20th.

Territorial Medical Officers.

Sir Clement Kinloch-Cooke asked the Under Secretary for War whether the recent order arranging for the promotion to captains of all lieutenants in the Royal Army Medical Corps included Royal Army Medical Corps' lieutenants of the Territorial Forces, and, if not, would he consider the advisability of their inclusion.—Mr. Tennant replied: No, sir, it is not intended to extend the arrangement referred to to the Territorial Force as the circumstances are not the same.

The Inoculation of Soldiers.

Replying to Mr. W. Thorne, Mr. Tennant said: The privilege leave given to inoculated soldiers who were shortly proceeding to the front, to enable them to visit their homes, was not extended to men who declined to be inoculated, and who were consequently selected to remain in this country. The manner in which an officer or soldier who seeks redress for any grievance is laid down in the Army Act, and any soldier or officer who adopts other methods, is guilty of a military offence.

Rum Rations.

Mr. Molteno asked the Under Secretary for War, whether, in view of the general consensus of opinion in regard to the desirability of restricting the use of alcohol, and particularly of ardent spirits, the Secretary of State for War would consider the desirability of ceasing to issue rum in large quantities to the troops at the front.—Mr. Tennant answered: The conditions under which rum is issued to the troops at the front have been fully explained on previous occasions. It is not proposed to make any change in the issue.

Medical Officers in the Navy.

Mr. George Terrell asked the Secretary to the Admiralty whether medical officers who had withdrawn from the service previous to the war and had received a gratuity on the scale laid down in the regulations now had deductions made on their pay as representing interest on the amount of such gratuity; and whether, in the absence of any authority for the making of such deductions, he would give instructions that all such officers are to receive their pay in full.—Mr. Macnamara wrote in reply: It is a long-established rule in the Navy that an officer in receipt of an annual retiring allowance should cease to draw that allowance on becoming entitled to full pay, &c., during re-employment whether in peace or war. The same principle is applied to officers who received their retiring or withdrawing allowance in a lump sum, and an amount representing the annual value of this gratuity is accordingly abated from their active service emoluments.

Notification of Births Act.

Sir William Byles asked the Parliamentary Secretary to the Local Government Board whether having regard to the effect of the war on the statistics of births and deaths he would consider whether, either by legislation or administrative order, the Notification of Births Act, 1907, now optional in character, could be made compulsory.—Mr. Herbert Lewis answered: The Notification of Births Act imposes no duty on local authorities to follow up investigations made under it, and unless this work is undertaken, the chief value of the Act is not secured. The Department have generally considered that it is preferable to persuade local authorities to adopt the Act and to carry out health visiting and other measures for the benefit of persons whose cases are brought to their notice in pursuance of the Act, rather than simply to put the Act in force compulsorily. I may add that the Act is now in force in respect of about 75 per cent. of the total population of England and Wales, and that the question of the adoption of the Act is now under the consideration of several areas.

Wednesday, April 21st.

Panel Practitioners and Military Duty.

Mr. Charles Duncan asked the Secretary to the Treasury what, if any, arrangements were being made to secure the administration of medical benefit under the National Insurance Act in cases where panel practitioners had engaged themselves for military duties.—Mr. Acland replied: In the circumstances referred to, the Insurance Committees have to be satisfied that as satisfactory arrangements as are possible, having regard to the heavy pressure on the medical profession, are made to provide for the continued discharge of the panel duties of absent medical men by means of locum-tenents or through their colleagues acting as deputies.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Cassie, Ethel, M.B., Ch.B. Edin., has been appointed Temporary Medical Officer of Health and Schools Medical Officer for Clackmannanshire.

Desmond, M. P., L.R.C.P. & S. Edin., L F.P.S. Glasg., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Slievereagh District of the county of Cork.

Henderson, J. M., M.B., Ch.B. Glasg., has been appointed Medical Officer to the Barrow-in-Furness Board of Guardians.

Jones, Charles Trickey, L.R.C.P. Irel., has been appointed Deputy Medical Officer for the Ilfracombe District by the Barnstaple Board of Guardians.

Macbean, A. F., M.B., Ch.B. Aberd., has been appointed Chief School Medical Officer for the county of Aberdeen.

Sinclair, R., M.B., Ch.B. Aberd., has been appointed Assistant Medical Officer for the county of Aberdeen.

Notes, Short Comments, and Answers to Correspondents.

A HEALTHY BRITISH DEPENDENCY.

THE Cayman Islands, forming a dependency of the colony of Jamaica, are situated between the meridians 79° 44′ and 81° 26′ parallels of 19° 41′ and 19° 46′ N., and consist of three islands—Grand Cayman, Cayman Brac, and Little Cayman—with a total area of 225 square miles. They are said to have been discovered by Christopher Columbus and to have been originally a rendezvous for pirates. The principal town is Georgetown, in Grand Cayman. The government is administered by a Commissioner, Mr. A. C. Robinson, who in his report for 1913–14, just received at the Colonial Office, states that the islands are among the healthiest places in the world. There are no cases of illness attributable to climatic conditions. The weather is warm for the greater part of the year. The prevailing breeze is from the south-east from April until October, and the cool season begins with a change of the wind to the north and north-west in the early part of November. In the hot months the average temperature is 83° F. in the morning, 89° at midday, and 86° in the evening; in the cool months (November to March) it is 71° in the morning, 80° at midday, and 74° in the evening. A census taken in June, 1911, showed the total population of the islands to be 5564. Of these 2322 are white, 2211 coloured, and 1031 black. 3087 were returned as able to read and write, 749 as able to read only, and 1728, including children, as illiterate. There are many islanders who attach no importance whatsoever to the education of their children and who do not consider even reading or writing as in any way essential to a child's future welfare. During 1914 there were 195 births, 99 males and 96 females. Of these 160 were legitimate and 35 illegitimate. In the same period there were 39 deaths, 21 males and 18 females. There is a small building kept for the purpose of isolating infectious diseases, but it is not generally used. Government medical officers are appointed for the Lesser Islands and Grand Cayman, whose duty it is to visit all the outlying districts. The mosquito season begins in April and continues until September, when they begin to abate, and from November to February almost disappear. Householders adopt the method of lighting a smoke fire to ward off the attacks of these insects, which swarm in myriads and render life a torture to man and beast. A few houses are mosquito-screened. There are fortunately very few of the anopheline or malaria-transmitting variety. Although these islands are practically immune from the recognised mosquito-borne diseases—as malaria, yellow fever, and filariasis—the mosquito is nevertheless seriously detrimental to the health in other respects, the conditions of anæmia and general debility met with being attributed by the Government medical officer to the blood-sucking power of these insects. Swamps are found in various places, but as these are below the level of the sea they could only be drained by a large expenditure of money. So far as it is possible to ascertain, the people generally seem to display a more marked interest in hygiene, and, as this subject is taught in all the Government schools and particular importance attached to it, the rising generation may be taught to realise to the full the benefits to be derived from living in healthy surroundings.

RABIES AND QUARANTINE FOR DOGS.

FROM time to time the newspapers report cases in which persons are summoned for endeavouring to evade the restrictions placed by the Board of Agriculture upon the introduction into this country of dogs from abroad, and it is fairly well known that ladies often bring, or endeavour to bring, small pet dogs in by smuggling them under cloaks and other garments. Such cases would not be in the same class as that of a dog which recently was brought to England from Northern Nigeria and fortunately was not smuggled, but was duly placed in quarantine where it sickened and died, subsequent investigation by the officers of the Board of Agriculture showing that the cause of death was rabies. The loyal acquiescence of all in the salutary regulations referred to is a public duty.

THE DANGER OF CARTS AS PLATFORMS.

A HORSE and van are often hired by orators who wish to address the public from a convenient moving platform in the open air, but there is a danger in so doing when standing at the rear of the cart facing the public, without sufficient protection from the tailboard as a small parapet, and without careful attention to the horse's head. This week several public recruiting meetings have been held in different parts of London, and one such meeting was addressed by a soldier supporting himself on two crutches, standing at the rear of a van. He called for one recruit to take his place in the ranks, and when one came forward there was clapping of hands. Simultaneously an electric tramcar passed, and probably the combined noises frightened the horse, which gave a jerk forward, with the consequence that the crippled soldier was thrown headlong on to the ground amidst the groans of the crowd. He might have been seriously hurt, but he was evidently plucky, for he rose again, and in a few minutes was assisted up and reoccupied his former dangerous position, although he was pale and evidently shaken.

WHISKY, ABSINTHE, AND BEER.

THE subject of "Drink and Prohibition" is now receiving much Government, public, and private attention. Whisky is the spirit chiefly consumed, perhaps, by the working classes. The "uisge beatha," "usque baugh," or "water of life," was originally known officially to the Government under the name of "aqua vitæ," and those who are interested in its history will find a few particulars in THE LANCET of Jan. 28th, 1905, p. 240, under the heading of "Definition of Whisky in the Olden Times," from which it will be seen that the Scotch did not fear their own product but did fear the admixture of nauseous foreign spirit as an adulteration. Before the Royal Commission on Whisky and other Potable Spirits, whisky was defined as "a spirit obtained by distillation from a mash of cereal grains saccharified by the diastase of malt," and no distinction was allowed between "pot-still" and "patent" spirit. Whisky is generally considered to be mild in effects compared with absinthe, which has lately been prohibited in France, but no whisky is mild which has not been well matured. It would certainly be of advantage that beer should take the place of whisky, but much beer is too strong. A light or lager beer is seemingly proposed to be brewed by direction of the Government and sold in this country, in place of the heavy beers. It is interesting to recall that by the 4th and 5th of Philip and Mary it was enacted that "No bere bruer to brewe nor sell to any typpler, or other person, any bere called doble doble bere, but only two sorts of bere—viz., best bere and small bere, upon forfeit of ye bere and cask." To understand this more fully it is necessary to recollect that the "typpler" was what we now call the "publican," and not the "constant toper" or the publican's frequent customer. The dangers of too strong beer have long been recognised, but it may not be easy to make a very light beer popular.

CHILDREN'S FRESH-AIR MISSION.

THE annual meeting of this mission will be held in Staple Inn Hall, Holborn, E.C. (by permission of the Institute of Actuaries), on Wednesday next, April 28th, at 4 P.M., when the Bishop of Islington will preside. The following speakers in support of the fund are announced: Alderman Sir W. H. Dunn, Miss Paget, Mr. W. Pett Ridge, and Mr. Ernest E. Wild, K.C.

A BELATED NOTIFICATION.

ON April 17th we received through the post from the Secretariat of the III. Internationaler Kongress für Gewerbekrankheiten, Vienna, the following notification:—

> August, 1914.
>
> DEAR SIR,—The International Congress for Occupational Diseases which had to take place between the 21th and 26th of September in Vienna, has to be given up on account of the state of war.—Yours faithfully,
>
> (Signed) Dr. TELEKY (?)

The exact date in August is, like the signature, undecipherable. The card, however, is surprisingly fresh and new-looking considering the time that it has been *en route*.

A USEFUL ANTISEPTIC SWAB.

WITH the object of minimising as far as possible the effects of septic poisoning of wounds received on active service, Dr. Campbell Highet, honorary medical officer to the Worcester Voluntary Aid Detachment, has devised a useful swab for applying an antiseptic solution. A glass ampoule is wrapped in a pad of plain gauze about 3 inches in diameter, and of 8 to 16 layers. The gauze is gathered round the thin neck of the ampoule, where it is tied with thread after the whole has been wrapped in an impervious covering. The ampoule holds half a dram or more of a solution recommended by Mr. G. Lenthal Cheatle, C.V.O., C.B., in the *British Medical Journal* (vol. ii., 1914, p. 1006), consisting of 1 in 20 carbolic acid and 1 in 500 mercury perchloride in absolute alcohol coloured with rosaline, the latter acting as a mordant. For use the ampoule is fractured by a sharp blow from any hard object, the impervious covering (which prevents leakage in case the glass container is accidentally broken) torn away, and the surface of the wound brushed with the impregnated swab. The swabs, which cost 2½*d*. each, are made by Messrs. J. Richardson and Co., and their inexpensiveness, portability, and easy manipulation should commend their use.

THE PAY OF GERMAN MILITARY MEDICAL OFFICERS.

"THE rate of pay of German military medical officers may be of interest to our own medical officers," writes a frequent correspondent. "The following appear to be the rates, unless they have been altered in any way since the war began. Sanitätsinspekteure, M. 10,260; generalärzte (surgeon-generals), M. 8772; general-oberärzte (colonels) and oberstabsärzte (lieutenant-colonels), M. 6102 to M. 6552; stabsärzte (staff-surgeons), M. 3400 to M. 5100; oberärzte (surgeons) and assistenärzte (assistant surgeons), M. 1700 to M. 2400; and unterärzte (subordinates or orderlies), M. 745. These are annual salaries, but may be supplemented by special house allowance, lodging allowance, or horse allowance. A mark may be reckoned roughly as a shilling."

DIABETIC CLINICAL CHARTS.

Messrs. J. B. Lippincott Company, of John-street, Adelphi, London, W.C., have submitted to us a convenient form of clinical chart fcr permanently recording the essential facts in regard to the urine, &c., in diabetic cases, both in hospital and private practice. They are printed on good paper, measuring 11 by 8 inches, and sold in packages of 50 at the price of 2*s*. 6*d*.

A. S. G.—One of the best tests for blood in urine is that devised by Meyer. It contains phenolphthalein, grm. 2; caustic potash, grm. 20; and distilled water, grm. 100. Mix and raise to boiling-point, then add powdered zinc, grm. 10; maintain at boiling-point for five minutes. Shake up and filter rapidly as soon as decoloration takes place. Add 1 c.c. of the reagent to a small quantity of the urine to be tested, also a few drops of peroxide of hydrogen when, if blood be present, a reddish colour is produced which is absolutely characteristic. With regard to the presence of urobilin in urine, Florence's test is easy of application and reliable: pyridine, alcohol, and chloroform āā 50 grm., acetate of zinc 7·50 grm. Add to the suspected urine twice its volume of the reagent and set aside. If positive a very characteristic fluorescence is produced.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Mr. H. Hartridge and Mr. A. V. Hill: The Transmission of Infra-red Rays by the Media of the Eye, the Transmission of Radiant Energy by Crookes's and other Glasses, and the Radiation from Various Light Sources (communicated by Mr. W. B. Hardy).—Mr. E. Beard and Mr. W. Cramer: Surface Tension and Ferment Action (communicated by Sir E. Schäfer).—Mr. W. Cramer: Surface Tension as a Factor controlling all Metabolism (communicated by Sir E. Schäfer).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

MONDAY.

SECTION OF ODONTOLOGY (Hon. Secretaries—F. Coleman, F. R. Smyth): at 8 P.M.

Adjourned Discussion:

On Dr. Ewan Waller's paper, The Influence of the Thyroid Gland on Dental Caries (published in the March number of the Proceedings of the Section of Odontology).

Paper:

Dr. J. Sim Wallace: The Principles of Dietetics.

SECTION OF MEDICINE.—The Members of this Section are specially invited to attend the discussion on Dr. Waller's and Dr. Sim Wallace's papers (as above).

SECTION FOR THE STUDY OF DISEASE IN CHILDREN.—The Members of this Section are specially invited to attend the discussion on Dr. Sim Wallace's paper (as above).

TUESDAY.

SECTION OF MEDICINE (Hon. Secretaries—John Fawcett, Charles R. Box): at 5.30 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1915-1916.

Papers:

Dr. Arthur J. Hall: Notes on (1) A Case presenting Symptoms of Lymphatic Leukæmia of Acute Onset terminating in Complete Recovery; (2) Some Cases of Myelogenic Leukæmia.

Dr. F. Parkes Weber: An Instance of Long Quiescence of Leukæmia.

To be followed by a discussion on the Treatment of Leukæmia

WEDNESDAY.

SECTION OF PSYCHIATRY (Hon. Secretaries—Bernard Hart, G. F. Barham).

A Clinico-Anatomical Meeting will be held at the Pathological Laboratory, Claybury Asylum, at 3.30 P.M.

Dr. Armstrong-Jones will show some cases of Hypothyroidism.

Dr. F. W. Mott, F.R.S.: Microscopical Demonstration of Changes in the Central Nervous System in Hypothyroidism.

Dr. Kojima: The Examination of the Thyroid Gland in 100 Successive Cases of Death, with Special Reference to Hypothyroidism.

Dr. F. W. Mott, F.R.S.: Microscopical Demonstration of the Choroid Plexus in Relation to Lipoid Constituents of the Epithelial Cells.

Dr. Sano: Anatomical Investigations regarding Speech Functions.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

MONDAY.—8 P.M., Cantor Lecture:—Dr. D. Sommerville: Foodstuffs. (Lecture I.)

HUNTERIAN SOCIETY, Barbers' Hall, Monkwell-street, E.C.

WEDNESDAY.—8 30 P.M., Annual General Meeting. 9 P.M., Dr. P. Stewart: Demonstration of Injuries to the Brain sustained during the War (illustrated by lantern slides).—Dr. C. J. Thomas will give an account of his Experiences in Germany during the War.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

ROYAL COLLEGE OF SURGEONS OF ENGLAND, Lincoln's Inn Fields, W.C.

Museum Demonstrations for Advanced Students and Medical Practitioners:—

MONDAY.—Mr. Shattock: Specimens of Diseases of Arteries.

POST-GRADUATE COLLEGE, West London Hospital, Hammersmith-road, W.

MONDAY.—10 A.M., Dr. Simson: Diseases of Women. [illegible] P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Dr. Pritchard: Bacterial Therapy Department. Mr. B. Harman and Mr. Gibb: Diseases of the Eye.

TUESDAY.—2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

WEDNESDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. [illegible] P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations. Dr. Simson: Diseases of Women. Mr. Gibb: Diseases of the Eye.

THURSDAY.—9 A.M., Dr. Bernstein: Bacterial Therapy Department. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. D. Armour: Operations. Mr. B. Harman: Diseases of the Eye.

FRIDAY.—10 A.M., Dr. Simson: Gynæcological Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Baldwin: Operations. Dr. Davis: Diseases of the Throat, Nose, and Ear. Dr. Pernet: Diseases of the Skin.

SATURDAY.—10 A.M., Dr. Saunders: Diseases of Children. Dr. Davis: Operations of the Throat, Nose, and Ear. Mr. B. Harman: Eye Operations. 2 P.M., Medical and Surgical Clinics. X Rays. Mr. Pardoe: Operations.

THE THROAT HOSPITAL, Golden-square, W.

MONDAY.—5.15 P.M., Special Demonstration of Selected Cases.

THURSDAY.—5.15 P.M., Clinical Lecture.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street, Piccadilly, W.

TUESDAY.—3 P.M., Mr. B. Fletcher: The War on Belgian Architecture. (Lecture III.)

THURSDAY.—3 P.M., Mr. A. W. Porter: Advances in General Physics. (Lecture I.)

FRIDAY.—9 P.M., Prof. F. G. Donnan: Emulsions and Emulsification (Experimental).

SATURDAY.—3 P.M., Tyndall Lecture:—Prof. J. A. Fleming: Photo-Electricity (Experimental). (Lecture I.) 5 P.M., Annual Meeting.

ROYAL SANITARY INSTITUTE, 90, Buckingham Palace-road, S.W.

WEDNESDAY.—5 P.M., Dr. W. P. Norris: The Evolution of Hygiene and Public Health in Australia.

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having [illegible] medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO [illegible] COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 [illegible]
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

METEOROLOGICAL READINGS.

(Taken daily at 8.30 a.m. by Steward's Instruments.)

An Address

ON

WOUND INFECTIONS

AND ON

SOME NEW METHODS FOR THE STUDY OF THE VARIOUS FACTORS WHICH COME INTO CONSIDERATION IN THEIR TREATMENT.

Delivered before the Royal Society of Medicine on March 30th,

By COLONEL SIR A. E. WRIGHT, M.D., F.R.S.,

A CONSULTING PHYSICIAN TO THE EXPEDITIONARY FORCE.

(*From the Research Laboratory attached to No. 13 General Hospital, Boulogne-sur-Mer.*)

(*Concluded from p. 847.*)

Treatment by Vaccine-therapy.

I emphasised at the outset of this discourse that Treatment by Vaccine-therapy could take rank only as ancillary to Treatment by Physiological Methods. In *treatment by physiological methods* we take the antibacterial agencies of the patient just as they are, and do our best to bring them into more effective application on the infective microbes. In *vaccine-therapy* we seek to reinforce those agencies. We endeavour to increase the bacteriotropic power of the blood, and to modify the chemotropic sensibility of the leucocytes. And, now that we have come to appreciate its importance, we should seek to increase also the antitryptic power of the blood fluids.

Let us try to see how the case for vaccines and vaccine-therapy stands, keeping always before us the great practical issue as to how much clinical benefit can in the particular case be secured for the patient, and arranging for the purposes of our survey the multifold applications of vaccines under six subheadings.

1. *Prophylactic employment of vaccines.*—This is not only from the theoretical point of view the best of all methods of employing vaccines, but it is also the method which gives in practice the maximum of advantage. We have only to look to the results obtained by prophylactic vaccination against small-pox, cholera, plague, and typhoid fever.

2. *Employment of vaccines in the treatment of localised bacterial inroads.*—Next to prophylactic inoculations, this gives the best results. And the results, in the respect that they are almost immediately manifest to the eye, are even more dramatic than those of any preventive inoculation. Perhaps the most rapid and convincing results are those obtained by small doses of streptococcic vaccine in lymphangitis and erysipelas; by staphylococcic vaccine in furunculosis, when the boil is just beginning to develop; and by minimal doses of tuberculin in phlyctenular affections of the conjunctiva.

3. *Employment of vaccines in dealing with unopened abscesses and other localised infections where the microbes cannot be reached from the blood stream.*—Vaccines are here, so far as appears to clinical inspection, quite inoperative.

4. *Employment of vaccines in the treatment of localised infections associated with heavy auto-inoculations.*—The scientific application of vaccines in these cases is extremely difficult and laborious; and the results which are obtained—and those obtained in the treatment of developed phthisis by tuberculin supply a good example—are not very convincing.

5. *Employment of vaccines in the treatment of undrained wounds infected by sero-saprophytes.*—There is not yet a sufficient body of experience to decide the question as to whether benefit can be obtained from vaccines in these cases. The question will be further discussed below in connexion with the wound infections of the war.

6. *Employment of vaccines in the treatment of septicæmic infections, and in particular streptococcic septicæmias.*—Up to the present—except perhaps in certain series of experiments relating to typhoid fever—vaccines have on the whole given very disappointing results. But it will be obvious to consideration, that as we advance through the whole series of applications—from prophylactic application to the employment of vaccines in septicæmias—the conditions are becoming progressively more difficult; so that success in treatment of septicæmias, if it is ever achieved, will be the very final achievement of vaccine-therapy.

We have now prepared the ground for considering what has been obtained by the use of vaccines in the treatment of wound infections in this war.

I have in connexion with this heard the opinion of a very distinguished French surgeon—pronounced after watching the effect of vaccines upon, I should think, undrained wounds and septicæmic infections—that they had never done any good. I shall, by my general survey above, at least have put you on your guard against generalising from one class of cases to all other cases. Let us now take each class of case separately, and ask ourselves whether in this vaccines have rendered any service. I think we shall then see that things work out everywhere in accordance with scientific law.

1. *Prophylactic inoculations of "antisepsis vaccines."*—If prophylactic inoculations of this kind have not been undertaken in our army, it has not been because a supply of antisepsis vaccines has not been at hand, but because the idea of undertaking such inoculations has not appealed to the individual medical officers who have given first aid to the wounded. And if any prophylactic inoculations have been undertaken, this can have been only on a very small scale; and the fact has not transpired. To be considered therefore here is only the question as to what we should on *a priori* grounds be justified in expecting from prophylactic inoculations against wound infections, undertaken upon the wounded. The answer is, I think, not doubtful. We might justifiably hope in a proportion of cases to sterilise the upper reaches of the wound which would be less heavily implanted; and perhaps in isolated cases—those in which we have a comparatively light sowing of microbes—to sterilise the whole wound. Moreover, if we could employ vaccines in combination with *physiological drainage* (I mean by that: free outpouring of lymph obtained by the use of a lymphagogic solution) we might, I think, hope to stave off infection in a fairly large proportion of cases. But—and I have already, though perhaps not emphatically enough, drawn your attention to this in connexion with prophylactic applications of antiseptics—it will, when we set out to sterilise a wound, nearly always be a question of achieving either all we want, or nothing. To leave behind, especially in the upper reaches of a wound, a few microbes, which immediately set to work and multiply, amounts, from the point of view of the future of the wound, to exactly

the same as leaving behind alive the whole original population. If one really intends a war of extermination there must be no remissions; and if our first effort with vaccines and physiological drainage fails, we must immediately follow up with further efforts.

2. *Employment of "antisepsis vaccines" in cases where the microbes make an irruption into the neighbouring tissues.*—It is in connexion with projectile wounds not very uncommon to see the infecting microbes breaking bounds, and making an irruption into the neighbouring tissues. This will occur either in a wound which has not been laid open, or where the lymph flow has stanched, and the microbes have been imprisoned in an infiltrated wall. The bacterial irruption may follow the course of the lymphatics as a lymphangitis; or it may take the form of an erysipelas or cellulitis. In these forms of infection occurring in connexion with projectile wounds, vaccines give exactly the same dramatic effects as in the small wounds of civil life—the only difference being that when the irruption has been beaten back we have in the case of projectile wounds still the original focus of infection to deal with; and have, unless we improve the condition of the wound, always to be upon our guard against a renewal of the irruption.

3. *Employment of "antisepsis vaccines" in connexion with well-drained wounds.*—When we have in a wound quite unobstructed mechanical drainage —such, for instance, as is proved by amputation without flaps—we have, from the point of view of the immunologist, conditions exactly parallel to those which obtain when microbes make a first irruption into healthy tissues. In other words, we have here—and probably also where we have good physiological drainage—brought to bear upon the microbes an ample force of phagocytes in conjunction with a rapid, as the case may be, percolating or outflowing stream of lymph. As a consequence, vaccines give in these cases results which are so strikingly favourable as to arrest the attention of every beholder.

4. *Employment of "antisepsis vaccines" in imperfectly drained wounds.*—An overwhelming proportion of projectile wounds which are under treatment in hospital would, regarded from the point of view of the mechanical conditions, come into the category of imperfectly drained wounds. And this is as it must be. The conservation of the wounded limb is clearly the first object of the surgeon; and the treatment of the bacterial infection is quite subordinate. For example, no one could ask that a leg which had been perforated by a bullet should be cut free from all its attachments to give better drainage to the infected track.

Now it might be legitimate to say that these undrained wounds were analogous to the unopened abscesses referred to above; were it not that this comparison would do much less than justice to the difficulties which confront the immunisator in the wound in which pus accumulates. Not only have we in the recesses and backwaters of such a wound conditions which make it impossible for the antibacterial agencies of the body to establish by their mass effect a position of superiority over the microbes; but we have in the corrupted discharges and the multiform bacterial growth which they harbour, obstacles to successful immunisation such as are never encountered in an unopened abscess cavity. It is therefore not to be expected that we should in these cases see—and in point of fact we do not see—after the exhibition of vaccines any diminution in the pus which pours from the wound.

None the less we shall do well carefully to consider in connexion with the employment of vaccines in the treatment of imperfectly drained wounds certain questions. It is clearly a matter for consideration whether—despite the fact that the output of pus from the wound is not diminished —there may not be some useful clinical result from the vaccines. It is quite likely that there is such an effect; and that it takes the form of a "nibbling" at the infection in those parts of the wound lying above the ground level of the pus; a better entrenchment against the microbes; and, behind this, a massing of reserves which would be brought to bear if the microbes were to irrupt into the surrounding tissues. In short, it is not unreasonable to think that the antisepsis vaccines might aid the surgeon in his conservative surgery, and might enable him to hold on longer when trying to save a limb.

Two further questions—questions which also cannot yet find answers—come up for consideration in this place. The one is the question whether it would not be possible in many cases to convert by physiological drainage an undrained, into a drained, wound, and then to obtain good results by the use of vaccines. The other is the question as to whether or no the bacteriotropic substances produced in response to antisepsis vaccines would come into operation upon serosaprophytic microbes in corrupted discharges, and in lymph whose antitryptic power has been artificially diminished.

5. *Employment of "antisepsis vaccines" in septicæmias supervening on wound infections.*—On this question there is nothing that can be usefully said other than that, until scientific knowledge has progressed much beyond where it is now, it might be well to act upon the suggestion made above with regard to the possible utility of antisepsis vaccines in staving off septicæmic infections.

We now at the end of our survey come to the summary.—That summary would clearly be, that the results of the inoculation of "antisepsis vaccines" have conformed in everything to scientific expectation. Of the five possible applications of vaccine-therapy, the *second* and the *third* have, according to anticipation, given strikingly favourable results. The *fourth* and the *fifth*—but perhaps certain reserves may be made in connexion with the *fourth*—have given, as anticipated, very unfavourable results. And that prophylactic employment of antisepsis vaccines, which has not yet been put to probation, would seem eminently deserving of an extended and careful trial, preferably in conjunction with physiological drainage.

EPILOGUE.

And now, except for a few concluding words, I have completed what I had to say. Up to this point we have considered only the scientific problems which confront us in wound infections. What we have now to consider is how this, and similar researches, and all that new clinical experience which has won in this war, can be made useful to the wounded.

This is a question of setting up machinery for directing and coördinating the work of the Medical Officers engaged in the treatment of the sick and wounded. And, I take it, on a question of that kind the Medical Profession at home will have a voice, and, if unanimous, perhaps even have a deciding voice.

In order to enable you to judge what changes in the system would be required to give effect to the idea that Medical Officers should bring into application the latest lessons of experience and science, I will venture to remind you how the Medical Service of the Army is at present organised.

We have in the Army Medical Service, as it seems to me, three different and distinct services—a *Service of Administration*, a *Service of Hygiene and Sanitation*, and a *Service for the Treatment of the Sick and Wounded.*

The Service of Administration—and among the three services it comes easily first in order of importance—takes charge of the wounded man on the battle field; conveys him first to the dressing station, field hospital, and clearing hospital which are ranged one behind the other at the front; thence transports him in an ambulance train to the hospitals at the base; afterwards embarks him in a hospital ship; and, at the end of his journey, provides him with hospital accommodation at home. The Service of Administration has further to see to the feeding, clothing, bedding, nursing, and medical treatment of the man in hospital, and in transit; has to look after all manner of surgical and medical stores and equipment—besides providing in a thousand other ways for the proper working of the hospitals and hospital camps.

The *Service of Sanitation* has to protect the army against epidemic disease by attending to water-supply, conservancy, and antityphoid inoculation. It has to keep a watchful eye on every case of infectious disease; to detect carriers; to equip, and man, the bacteriological laboratories required for this purpose; and to intervene in ways too numerous to mention to prevent the dissemination of infection.

The duties in connexion with the aforesaid services devolve almost exclusively upon the permanent officers of the Royal Army Medical Service. Their work, as everyone at the seat of war knows, has been quite marvellously well done. And what stands already very high in the esteem of all the world, needs no more words of praise from me.

There remains the *Service for the Treatment of the Sick and Wounded.* After supplying all the multifarious duties just enumerated, there are very few Medical Officers of the permanent staff of the Royal Army Medical Corps left over. Hence nearly the whole care of the sick and wounded has fallen to the Civil Practitioners enlisted for temporary service with the Royal Army Medical Corps. For this, if for no other reason, it must be the special concern of the Civil Profession to do all that in it lies to help the Medical Staff of the Army to employ to the best advantage the Civil Practitioners now serving as Medical Officers in Military Hospitals.

What has been done in the way of regulating the work of these new-joined medical officers, has been to transplant practically unaltered into the military hospitals the organisation under which medical practitioners work in civil life and in peace.

The treatment of the sick and wounded is committed, as it is in private and hospital practice at home, into the hands of individual practitioners, there being assigned to each a certain number of patients, or a ward. And just as at home, each medical man is in practically independent charge of his cases, and is free to follow whatever treatment appeals to him; so is it in the Military Hospitals. And just as at home the free exercise of private judgment carries with it an exclusive responsibility, saving only in those cases where a consultant is called in to advise; so also is it in the Military Hospitals.

Now, I submit that this unchartered freedom can work for good only in conditions such as those which surround us at home. At home, the practitioner finds himself practically always upon ground with which he is familiar. The cases which he deals with in his practice are similar to those he has seen treated in hospital. And if he should find himself upon unfamiliar ground he will, before he need take action, have time to inform himself. Moreover, though new science filters in slowly, it does filter in. And, finally, when the medical practitioner at home makes a new experiment in treatment, he—and this is the all-important point—does learn what results. He can therefore profit from the teachings of experience.

Now, the conditions in military hospitals abroad are quite different from these. The practitioner is there on quite unfamiliar ground. He has to confront unfamiliar problems—problems in connexion with projectile wounds and wound infections. He has to take immediate action. He has very little opportunity to find out what has happened in similar cases. And lastly—and you will see that upon this point everything pivots—has very little opportunity of seeing the results of his work, and learning whether his treatment has been wrong or right. For the military hospitals in France, both at the front and also at the base, have now, through military necessity, become little more than clearing hospitals, from which cases, if at all fit to travel, are immediately sent forward upon their homeward journey.

There are thus lacking in the military hospitals in France all those provisos and safeguards which alone can make a system in which each medical man is a guide to himself successful. And carried out without those safeguards that system is unjust both to doctor and patient.

The doctor feels himself left in the lurch when he is not warned off from trying experiments in treatment which a hundred others have unsuccessfully tried. He fain looks for a lead where a successful treatment has been discovered. And, where there are a number of alternative treatments, he would be glad to see comparative experiments instituted to tell him which method is best. Nor is the doctor the only person interested. The patient, his relatives, and the whole nation would, once their thoughts were directed to the matter, feel that they had the vital interest in making the work of the medical officer as effective as possible.

If this is to be done it will, I believe, be necessary to make a fundamental change in the organisation of the Medical Service—to break away from the principle of free arbitrament in treatment for the Medical Officer, and to provide that all treatment shall be regulated by orders and instructions.

These are, as you see, very big issues. It is a question of a conflict between our cherished professional tradition that every medical man must be quite unfettered in his choice of treatment; and the very foundation principle of the Army, that every man shall work, not as he individually thinks best, but as part and parcel of a great machine.

The question as to which of these shall give way to the other must, of course, be decided by the balance of public advantage. And we cannot seriously doubt to which side that balance inclines. We have only to consider what has been achieved in this war by antityphoid inoculation, and the preventive injection of antitetanus serum; and to compare the brilliant results of these measures, carried out as they are by direct instructions from headquarters, with the results which would have been obtained if the carrying out of these measures had been committed to the individual arbitrament of medical men who had not had before the war any opportunity of convincing themselves by personal experience of the utility of either antitetanus or antityphoid inoculation.

If now, as we see is the case, considerations of public utility commend the control of treatment of the sick and wounded by orders and regulations, let me in conclusion very briefly consider with you how under such a system there might be obtained a maximum of advantage with a minimum of disadvantage. I shall, of course, indicate only in very broad outlines what would seem to me to be the requirements.

I believe there would require to be a Professional Head to the Service for the Treatment of the Sick and Wounded. He would, of course, be subordinated to the Director-General, and his duties would be to bring up the work of the medical officers everywhere to the highest standard, and to coördinate their work from hospital to hospital.

It would further, I think, be necessary to have an Advising Committee who should be charged with the duty of synopsising the clinical experience won in the war; of finding out what results the various therapeutic procedures had given; and of drawing up on the basis of these inquiries general instructions and recommendations for the treatment of different categories of cases. On a Committee of this sort one would, of course, wish to see representatives of surgery, of medicine, of the various specialities, and of pathology and bacteriological science. But one would wish to see the membership restricted to those who were actually at work at the seat of war, and who were prepared to take full responsibility, and carefully to watch the working of the recommendations, and at any moment to revise them in the light of accumulating experience, or further laboratory experiments.

Finally, one would wish to see attached to such a committee a Research Department for the resolution of all bacteriological questions arising in connexion with hygiene, surgery, and medicine. And I may perhaps be allowed, in connexion with this last, to point out that the Medical Research Committee of the National Insurance Act, under whom I have the honour to serve as Director of Bacteriological Researches, has since the outbreak of the war been placing not only large funds but a carefully selected corps of skilled workers at disposal for the prosecution of researches directly contributory to the better treatment of the wounded. It is for you to see that the results, as they are obtained, shall be taken full advantage of.

New Convalescent Home for Soldiers.—On April 23rd Mrs. Mildmay, wife of Colonel F. Mildmay, M.P., formally opened a new convalescent home for soldiers at Salcombe, Devon. The home has been given as a memorial by the parents of the late Lieutenant R. N. Vereker, of the Grenadier Guards. It stands on three acres of ground on the slope of Bolt Head, and will provide accommodation for 25 soldiers. The institution will be worked by the British Red Cross Society, Dr. H. Wilcox being the medical officer.

ABSTRACT OF

Hunterian Lecture

ON

ILEUS DUPLEX

(INFLAMMATORY ENTERO-COLIC ILEUS).

Delivered before the Royal College of Surgeons of England on March 8th, 1915,

By W. SAMPSON HANDLEY, M.S. Lond., F.R.C.S. Eng.,

HUNTERIAN PROFESSOR; SURGEON, WITH CARE OF OUT-PATIENTS TO THE MIDDLESEX HOSPITAL; CAPTAIN, R.A.M.C. (T.F.)

Mr. President and Gentlemen,—On the four previous occasions when the Council of this College has honoured me by election as a Hunterian Professor I have brought before you work which was the joint product of the laboratory and of the hospital ward. I believe that every surgeon who wishes to advance his subject ought throughout his career to spend a portion of his time in the laboratory, following in this respect the great example of Lister. But the segregation of pathology from practice has unfortunately tended to the exclusion of the clinician from the laboratory, and thus it comes about that he is more and more restricted to the field which Moynihan has described as the pathology of the living. On the present occasion I wish to bring before you some gleanings from that field.

Nature and Causes of Ileus Duplex.

Adynamic or paralytic ileus is a condition in which non-mechanical intestinal obstruction results from muscular paralysis of a length of the intestinal canal. Most surgeons recognise it, though some deny its existence. The best classification of its causes is given by Murphy[1]: (1) Muscular paralysis from trauma or exposure; (2) local traumatic peritonitis; (3) local or general septic peritonitis; (4) embolism of the mesenteric vessels; (5) pylephlebitis; and (6) strangulation of pedicles by mass ligatures with reflex intestinal paralysis.

Though adynamic ileus is well recognised, it nevertheless remains a kind of limbo to which obscure cases may be relegated. The subject is surrounded by that indefinable haze, the result of imperfect knowledge, which, to the despair of the student, envelops certain chapters of surgery, such, for instance, as those dealing with shock or with osteo-arthritis. It can only be clarified by patient methods similar to those which have lately been applied to the group of insects known indiscriminately to Artemus Ward as "skeeters." My attempt to-day is to pin out and dissect one variety of adynamic ileus which has characters so definite that it needs a distinctive name. For reasons which will appear I propose to call it ileus duplex. Let me remind you that the word "ileus" is a synonym for intestinal obstruction, and that it has no connexion with the word "ileum."

In order to place you at once in possession of my point of view, and to enable you to weigh the evidence later to be adduced, I shall begin by giving a brief dogmatic description of this condition.

Definition.

Ileus duplex is a condition in which, as the result of a pelvic peritonitis, there is obstruction of the intestine at two points: (*a*) in the ileum, at a point about 3 ft. above the ileo-cæcal valve; and (*b*) in the sigmoid colon at the junction of its iliac and pelvic portions. These are the points at which the ileum and colon respectively cross the brim of the true pelvis to enter the pelvic cavity. (See figure.)

---

[1] J. B. Murphy, Keen's Surgery, vol. iv., 1908.

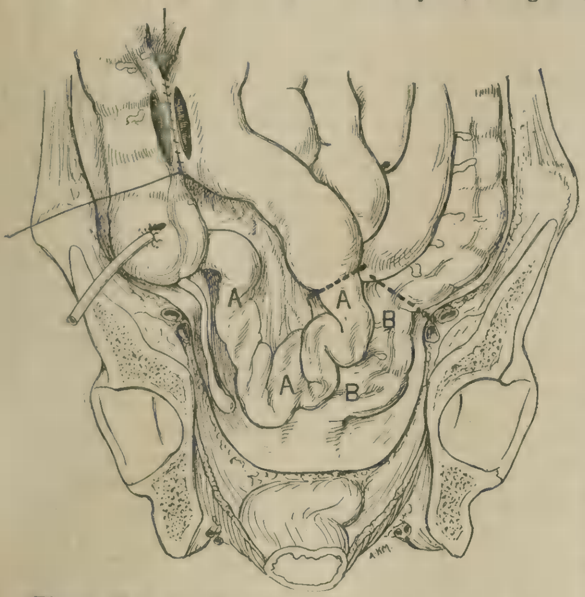

Diagram illustrating the pathology and treatment of ileus duplex. AAA, The paralysed segment of ileum. BB, The paralysed segment of the pelvic colon. The dotted lines indicate the level of the obstruction in the small and large intestine. A lateral ileo-cæcostomy is being performed between the distended ileum well above the obstruction and the cæcum. To relieve the temporary obstruction of the large intestine a catheter has been tied into the cæcum. The catheter is subsequently brought out through the abdominal wall.

The segments of intestine paralysed are two in number: first, the portion of ileum contained in the pelvis—that is to say, about the lower 3 ft., excluding the last 2 in.; and secondly, the portion of the large bowel contained in the true pelvis—i.e., the lowest portion of the pelvic colon and the upper portion of the rectum.

On account of the special liability of the pelvic peritoneum to bacterial invasion my subject is one of great importance. I deem it worthy of your attention for three main reasons: first, because the condition, though curable by appropriate treatment in the early stage, often passes unrecognised under the pseudonym of general peritonitis; secondly, because the duplex character of the obstruction, as indicated in my title, has not hitherto been appreciated; and thirdly, because, as might be expected, defects in the pathological conception of the condition have been reflected in imperfect treatment. And in this condition delayed or defective treatment means certain death.

Etiology.

Ileus duplex may result from any one of the many causes of pelvic peritonitis. Restricting myself to those causes included within the scope of my own experience, it may result from: 1. Appendicitis. 2. Ascending infection of the genital tract, gonorrhœal or septic. 3. Rupture of the bladder. 4. Carcinoma of the rectum. To these classes may be added from the experience of my gynæcological colleagues, Messrs. Berkeley and Bonney.[2] 5. Septic conditions of the pelvic genital organs or operations for their relief (pyosalpinx, carcinoma of the cervix). It seems likely that further experience will extend the list of causes which I have considered.

Appendicitis is by far the most frequent cause of ileus duplex, and for obvious reasons nearly always the appendix is pelvic in position. The special liability of pelvic appendicitis to give rise to ileus duplex joins with ambiguity of its earlier symptoms to make it perhaps the most dangerous form of the disease. I believe that its present mortality can be very appreciably lowered by a general recognition of the danger.

MORBID ANATOMY OF ILEUS DUPLEX AS OBSERVED DURING LIFE.

It frequently happens in cases of pelvic peritonitis that pus is found in the pelvis lying free among practically normal coils of ileum, which though congested have not lost their lustre. The bowel may contain gas, its wall is not œdematous, it has evidently not lost its motor power. The peritonitis remains superficial, and the wall of the gut does not become inflamed. Drainage of the pelvis, and the subsequent use of turpentine enemata, suffice for the successful treatment of such cases, which form a large majority of cases of pelvic peritonitis.

In other cases, and these alone interest us to-day, the coils of the pelvic ileum, bathed in pus, show evidence of acute inflammation of the bowel wall. Their peritoneal surface is dull, intensely congested, and covered with pus and flakes of lymph. The bowel wall itself is swollen and œdematous. The affected coils are empty, passively contracted and motionless, and between adjacent coils are sharp angular kinks sometimes fixed by flakes of sticky lymph. My colleague Victor Bonney, who gave what is perhaps the earliest detailed description of the condition of the ileum in these cases,[3] noted that the bowel is flattened like a strap, and he found that it is impossible by manipulation to force the gas from the intestine above into the inflamed segment of ileum, an important observation directly showing the impermeability of the inflamed bowel.

The conditions described, which involve the lower two or three feet of the ileum, immersed in the pelvic basin of pus, extend to within about two inches of the ileo-cæcal valve. The terminal two inches of the small intestine extending from the brim of the pelvis to the ileo-cæcal valve is usually collapsed and normal.

This condition of the pelvic ileum may, no doubt, coexist with a hopeless general peritonitis involving the whole area of the peritoneum. But in the cases we are considering the suprapelvic abdomen, though often not shut off by any lymph barrier, affords no sufficient evidence of peritonitis except to one obsessed by a preconceived idea. The pelvic ileum only is inflamed. Higher up the ileum presents its normal shiny appearance or is at most slightly congested. No pus is present amid its coils. A fairly sharp boundary line separates it from the inflamed pelvic ileum. If the case is an early one distension is absent. Soon, however, the suprapelvic ileum begins to be distended, owing to the block produced by paralysis of the pelvic ileum. It fills from below upwards, for I recollect one case in which the jejunum was still empty while the ileum was distended. But in what may be regarded as the typical stage of ileus duplex the suprapelvic small bowel, though quite uninflamed, is greatly distended owing to the obstruction lower down. That in this stage it is not paralysed is shown by the results of treatment.

---

[2] Victor Bonney: On Post-operative Paralytic Obstruction of the Intestine, with Special Reference to its Treatment by Jejunostomy, Archives of the Middlesex Hospital, vol. xxi., p. 39.

[3] Loc. cit.

It must be clearly recognised that distension of the suprapelvic small bowel even when accompanied by slight congestion is not adequate evidence of general peritonitis. If, however, the case is allowed to run its course paralysis of the distended intestine supervenes, bacterial penetration of its walls occurs, and a general peritonitis may be found at the necropsy.

We must now turn to the condition of the large intestine. Usually at the time the operation is performed the large intestine shows no evidence of inflammation, perhaps because it is situated further from the inflamed appendix, and shielded from early infection by the ileal coils. Clinical evidence, however, shows conclusively that in the course of a few days the pelvic colon, though its involvement is later and less constant than that of the pelvic ileum, shares in the inflammation and paralysis which have already overtaken the small bowel. To this point I shall later return, for its recognition is essential to success in treatment.

The portion of the large bowel, situated between the ileal obstruction and the obstruction in the pelvic colon, usually contains some flatus and is neither collapsed nor distended.

PATHOLOGICAL ANATOMY.

In many cases after death the necropsy fails to reveal the real secret of the condition. What is found is a general peritonitis with general paralytic distension of the intestinal tract, a misleading confirmation of the usual diagnosis made during life. At the time it was made this diagnosis was nevertheless incorrect. No series of necropsies can establish the morbid anatomy of ileus duplex. In it two processes—namely, a spreading peritonitis of pelvic origin and an intestinal obstruction—are running a race. In the early stages seen by the surgeon the obstruction is well ahead, and there is no peritonitis above the pelvic brim. In the post-mortem room stage the peritonitis has had time to overtake it, and may be more or less generalised. Moreover, since obstruction ends in peritonitis and peritonitis in obstruction, it may pass the wit of man to say after death which was the primary and which the secondary cause of death. The recognition of ileus duplex is a product of operating-theatre pathology, not of dead-house pathology, and supplies one more example of the truth of Moynihan's belief that intra-vitam rather than post-mortem inspections are at the present day the key to further advances in knowledge.

CLINICAL SIGNS AND SYMPTOMS.

The signs and symptoms of ileus duplex are those of acute intestinal obstruction, superposed on those of the pelvic inflammation which has caused it. A detailed description is perhaps superfluous, but a few special points need emphasis. Vomiting, though not invariably an early symptom, is almost a constant one. An initial vomit is the rule in appendicitis, but continued vomiting is very exceptional. It is a most useful danger-signal. When repeated vomiting occurs the possibility of ileus duplex must be promptly considered, and careful instructions must be given to the nurse to watch for and record the passage of flatus. The cessation of flatus, in spite of enema and the use of the rectal tube, establishes the diagnosis of intestinal obstruction, and if the subcutaneous injection of eserine fails recourse must be had to operation. Owing to the late and slow onset of the large intestine paralysis enemata may at first succeed in relieving the paretic colon. If subsequently vomiting and other symptoms persist this delusive success must be ignored, or surgical intervention will come too late.

In typical cases there is moderate general distension of the abdomen, but owing to the acute onset of the obstruction no opportunity occurs for those intestinal gymnastics which produce visible coiling in obstructions of slower development. Visible peristalsis is absent. Abdominal rigidity is also absent, except possibly in the hypogastric region. This absence of rigidity is a salient and important point in ileus duplex.

Abdominal rigidity depends upon inflammation of the parietal peritoneum of the anterior abdominal wall, and in operable cases of ileus duplex this district of the peritoneum is not inflamed except at its hypogastric margin. Care must be taken not to mistake for true rigidity that tension of the abdominal wall which results from the intestinal inflation. Abdominal respiration is embarrassed by the general distension, but is still present.

In untreated cases the later signs merge completely into those of general peritonitis.

PROOF OF THE DUPLEX CHARACTER OF THE OBSTRUCTION.

Let me now attempt to justify the dogmatic statements I have made.

Inflammatory obstruction of the lower ileum is a well-recognised condition, and this lecture will fail in its principal object if I fail to prove that in most cases of the kind there is also an obstruction in the pelvic colon. To this point I must now direct your attention.

Failure of Treatment if Directed Solely to the Ileal Obstruction.

In cases of obstruction of the lower ileum I have found by experience that a lateral anastomosis between the ileum some little way above the point of obstruction and the cæcum or ascending colon is, on the whole, a very successful method of treatment except in ileus of inflammatory origin. The table which follows indicates my experience up to about 1908.

TABLE I.—*Cases of Acute Obstruction of the Lower Ileum treated by Ileo-cæcal Lateral Anastomosis.*

	Number of cases.	Deaths.	Recoveries.
Obstruction by the appendix acting as a band (appendix also removed)	5	0	5
Obstruction by bands	3	1	2
Inflammatory ileus secondary to pelvic inflammation ...	5	4	1

This table shows an extraordinary difference in the prognosis of obstruction of the lower ileum according as the obstruction is inflammatory or non-inflammatory. The contrast is even more striking than the table would indicate, for the fatal case of "obstruction by band" recovered from the operation, only to die from phthisis.

The extraordinary difference in the prognosis of non-inflammatory and inflammatory cases might be explained by assuming that death in the inflammatory cases is due to general peritonitis and not to obstruction. But, as we shall see, clinical observation does not bear out this view.

The contrast between my successful results in cases of obstruction by band and my mortifying record of failure in inflammatory ileus puzzled and depressed me. It seemed clear that in inflammatory ileus an unrecognised factor was at work, but I was unable to identify it, and the text-books did not assist me. The first ray of light on the problem came in 1910 from the following case which I shall ask you to allow me to consider in full.

Pelvic appendicitis; ileus duplex; ileo-sigmoidostomy; recurrence of symptoms of obstruction; cæcostomy; recovery (*Case 8*).—At the request of Dr. W. M. G. Glanville, of Hampstead, I saw with him in 1910 an old lady of about 70, suffering with acute abdominal pain rather more severe on the right side than on the left, but not definitely localised in the right iliac fossa. Chronic constipation had been a marked trouble. The temperature was slightly raised and the pulse somewhat quickened. These symptoms had been present for about 24 hours. There was no abdominal rigidity, nor could any tumour be felt in the right iliac fossa. There was in this region some tenderness on deep pressure. No tenderness was elicited on vaginal or rectal examination. On opening the abdomen in the middle line, within 24 hours of the onset of symptoms, I found a gangrenous appendix hanging down into the pelvis. It proved to be impossible to remove it without making a second incision in the right iliac fossa. The coils of the pelvic ileum were intensely congested, but there was no pus present, nor did there seem to be any indication that the congested ileum was paralysed.

During the succeeding 48 hours, although the patient's pulse and general condition were fairly good, no flatus was passed, and the abdomen became much distended. It was obvious that there was complete inflammatory obstruction of the lower ileum, and that the patient would die unless something further was done. The median wound was opened up, and a lateral ileo-sigmoidostomy was performed as quickly as possible. Dr. D. Embleton, pathologist to the University College Hospital, was asked to examine the pus, and on his advice a large dose of antistreptococcic serum and a stock vaccine of staphylococcus aureus were administered shortly after the operation. Sixteen hours later no flatus had passed, and the patient's condition was extremely grave, indeed apparently hopeless. The pulse had become very rapid and feeble, and abdominal distension had increased. Small doses of calomel by the mouth caused sickness, and turpentine enemas were ineffectual. Dr. Glanville urged that strong purgatives should be administered, and to this course I consented because I thought the case was hopeless. He carefully passed a stomach-tube, but it was repeatedly returned. Another anæsthetic was therefore given 60 hours after the first operation, so that the stomach could be washed out and placed in a condition to retain purgatives. Dr. Glanville then administered through the stomach-tube 5 grains of calomel, an ounce of magnesium sulphate, and a minim of croton oil. These heroic measures were followed the next morning by a copious evacuation and the patient's condition then began to improve, although there was suppuration of the incisions owing to the virulence of the bacteria. An autogenous vaccine was prepared by Dr. Embleton and administered, apparently with good results. A week later, however, abdominal distension recurred and became extreme, although flatus in small quantities continued to be passed. Partial obstruction evidently persisted, and paresis of the sigmoid below the ileo-sigmoidostomy was apparently the cause of it. I therefore opened the cæcum through the wound without an anæsthetic and tied in a catheter. The relief was immediate. From this time the patient slowly recovered strength, and she is now in excellent health, has been able to take a long railway journey, and is free from the chronic constipation which had troubled her for years before the operation. The cæcostomy closed spontaneously.

I have never seen a case recover in which death appeared so imminent and certain. The main part of the credit belongs to Dr. Glanville, who refused to despair when I had given up hope, though I may congratulate myself that my ileo-sigmoidostomy was able to stand the strain imposed upon it by his heroic and almost veterinary cathartics.

Evidence afforded by Two Crucial Cases.

The successful result of this case clearly indicated to me the reason of my previous failures. In my early cases I had been dealing with one obstruction and had ignored a second. My tentative and halting treatment of this case is obviously open to criticism in the light of my present knowledge. But it has this great value, that it affords an experimental dissection of ileus duplex into its three pathological elements of pelvic peritonitis, ileal obstruction, and colic obstruction. It is a crucial instance. In the first operation the peritonitis and its cause were treated. In spite of this the morbid picture continued to develop, and obstruction became manifest. The second operation short-circuited the small intestine obstruction. Its success was temporary only, and the purgatives which followed it produced but a transient result. The third operation, aimed at an assumed obstruction in the colon, gave immediate and permanent relief. In the first two stages the conditions present within the abdomen were determined by direct inspection.

The history of this case has a demonstrative value rare in clinical work, and only attained as a rule in precise and carefully planned laboratory experiments. Let me remark especially that it clearly indicates three stages of the obstruction in ileus duplex: (*a*) Stage of obstruction of the ileum alone; (*b*) stage of obstruction of the ileum with paresis of the colon; and (*c*) stage of complete obstruction of both ileum and colon. The late onset of the colic obstruction is an important point to which I must return.

But it is frequently said that one case proves nothing. Let me then draw your attention more briefly to a second and later case.

This case, too, was one of pelvic appendicitis in a woman of middle age, in which, though the pelvic ileum was inflamed and congested, no evidence of intestinal obstruction had manifested itself prior to the first operation. I accordingly contented myself with the removal of a gangrenous appendix and the drainage of a pelvic collection of pus. On the fifth day after the operation complete intestinal obstruction developed. The abdomen was reopened, a lateral ileo-colostomy was performed, and, in view of the lessons of the previous case, a catheter was tied into the cæcum. After a severe struggle the patient recovered.

So far this case has less probative value than the preceding one. The colic obstruction was not obvious at the operation, and a critic might assert that it would have been sufficient to short-circuit the inflamed ileum without providing any relief by the cæcostomy for a purely hypothetical colic obstruction lower down.

A very instructive incidence of this patient's convalescence effectually disposes of the criticism. Shortly after the spontaneous closure of the cæcostomy opening the abdominal distension recurred. It could not be overcome by purgatives or enemata, but after reaching a serious degree it was relieved by the spontaneous bursting open of the recently healed cæcal fistula.

It is impossible to inflict upon you detailed accounts of all my cases. Anticipating what I have to say on treatment, let me then point out Table II., which shows that, if treatment is directed only to one of the two obstructions present, death may be expected in 75 per cent. of cases. But if my hypothesis of a double obstruction is acted upon the mortality falls to 20 per cent. The evidence for the duplex character of the obstruction derived from the two crucial cases I have given you in detail is thus borne out by the appeal to statistical results. The fact that no two blades of grass are precisely alike, still less two cases of disease, is the fallacy of all statistics, which relegates them to the place of secondary or confirmatory evidence. The precise study of single cases is, in my opinion, of much greater value. But when, as in this instance, the one method of investigation confirms the other a high degree of certainty is reached.

PREVENTION OF ILEUS DUPLEX.

Although, thanks to a general recognition of the need for prompt operation in appendicitis, the mortality of that disease is now becoming a residual one it is susceptible of further reduction if the danger of ileus duplex is borne in mind in cases where the appendix is pelvic in position. It is of great importance to detect and treat infection of the pelvis in its earlier stages.

In every case of appendicitis, unless it is certain that the mischief is securely shut off by adhesions and confined to the right iliac region, a small median subumbilical incision should form the first step of the operation. With a pair of sponge forceps a fold of gauze is carried to the bottom of the recto-vesical or recto-uterine pouch. If no inflammatory fluid is present on the gauze when withdrawn the finger with great caution explores the limits of the inflammatory mass in the right iliac region, thus gaining valuable information. The incision is then sewn up, and the appendix subsequently removed through an incision made over it in the usual way.

If the rule thus laid down be carried out, in a certain proportion of cases, even of localised appendix abscess, unsuspected dirty or semi-purulent fluid will be found free in the pelvis. By the introduction of a drainage-tube through the median exploratory incision to the bottom of the recto-vesical pouch these cases will be saved from the pelvic abscess, or spreading peritonitis, or ileus duplex which they would probably have developed if the median incision had not been made.

When pelvic infection is found it is a matter to be decided in each case whether to prolong the incision and remove the appendix through it, or to make a subsequent second incision directly over the offending organ.

Two other points must be borne in mind for the prevention of mortality from ileus duplex. At every operation for pelvic appendicitis the ileum must be examined for inflammatory paresis and the suprapelvic ileum for distension. After every appendix operation the nurse must be instructed to report carefully on the passage of flatus, for early recognition of ileus duplex is essential to its successful treatment.

TREATMENT.

The treatment of ileus duplex may be conveniently studied in the light of Table II., which records the results of my experience during a period of eight years. The condition is neither rare nor common. I have met with it 14 times among some hundreds of abdominal cases of all kinds. Though the figures of my table are small, they are, I think, very significant as to the merits of different modes of treatment. They show especially that forms of treatment which take into account only the small intestine element in the obstruction give a high mortality. Thus 4 out of 6 cases of simple ileo-cæcostomy died. The two cases which recovered indicate that the large intestine obstruction, besides being later in onset, may not always become complete.

TABLE II.—*Results of Treatment in the Lecturer's Cases of Ileus Duplex, 1907-1915.*

	Recovered.	Died.
Enterostomy	0	1
Enterostomy with ileo-cæcostomy ...	1	0
Ileo-cæcostomy alone	2	4
Ileo-sigmoidostomy	0	1
Colostomy alone...	0	1
Ileo-colostomy with cæcostomy* ...	3	0

* In one of these cases the cæcostomy was performed some days after the ileo-colostomy on account of the persistence of symptoms, and with immediate relief.

On the other hand, I have no death to record among the 3 cases treated by ileo-colostomy combined with cæcostomy. This is the ideal treatment. It appears to matter little whether the anastomosis is made between the ileum and cæcum or the ileum and sigmoid, provided in either case that a safety valve to the exterior is supplied by tying a catheter in the large intestine. I believe the anastomosis with the cæcum is safer as being further removed from the inflamed area.

On a recent occasion, forgetful of the results of my own experience, I performed an ileo-sigmoidostomy for ileus duplex without draining the cæcum. The case was one of pelvic appendicitis in a woman of advanced years, with mingled signs of pelvic peritonitis and obstruction. The pelvic ileum was obviously paralysed, but at the time of operation the pelvic colon wore a deceptively normal appearance. Lateral anastomosis of the suprapelvic ileum with the sigmoid was followed by some days of complete relief. But the anastomosis, subject to the strain of oncoming paresis of the pelvic colon, finally yielded, and the patient died from septic peritonitis and fæcal extravasation. So difficult is it not to forget the lessons of one's own experience.

In at least one of my cases treated by ileo-cæcostomy and cæcostomy natural actions of the bowels per anum occurred within a day or two of the operation. This must not be taken to prove that the drainage of the cæcum was unnecessary. It has already been shown that the colic element of the double obstruction is late in its onset, and it must be obvious, moreover, that drainage of the cæcum will relieve distension of the large intestine, and will thus facilitate its blood-supply and tend to *prevent* paralysis of the pelvic colon.

I am prepared to admit that a cæcostomy is superfluous in a minority of cases. The recovery of two of my cases of ileo-cæcostomy, cases in which the cæcum was not drained, shows that the third stage, that of paralysis of the pelvic colon, does not constantly follow the others if the peritonitis is treated by pelvic drainage. But it cannot be right to trust to this in any particular case. My figures indicate that the surgeon who trusts to ileo-cæcostomy and peritoneal drainage alone will repent his decision in at least two out of three cases. If obstruction persists he may still be able to save the patient by a timely cæcostomy, as one of my cases shows, but the undesirability of secondary operations in acutely ill patients is so generally recognised as to need no emphasis. It is far better to perform simultaneous cæcostomy as a routine precaution in all cases where an ileo-cæcostomy is necessary.

The Colostomy Opening.

In dealing with the large intestine element of the obstruction it is to be borne in mind that the obstruction is temporary only, and that in cases which recover within ten days or a fortnight at most the large bowel will have recovered its propulsive power. If during this period provision is made for the escape of gas it appears to be unnecessary to provide for any evacuation of solids, especially as the patient will be taking only small amounts of food. For these reasons it is unnecessary to make a full-sized colostomy opening, and all needs will be met if a large rubber catheter is passed through an aperture in the wall of the colon and held in place by a purse-string suture, which also transfixes the catheter. It probably matters little whether the catheter is introduced into the cæcum or at any lower point situated above the pelvic colon. As a matter of convenience, when an ileo-cæcostomy has been performed the cæcum is the most accessible point to choose. Probably the best form of catheter is a so-called "self-retaining female catheter," since this is less likely to be blocked by fæcal débris. Should the cathether become blocked it must be cleared by syringing through it a small amount of saline. The catheter will come out spontaneously about the fifth day, and a small fæcal fistula remains which will rapidly close as soon as it has become superfluous.

Enterostomy.

The old treatment of enterostomy will, no doubt, occasionally save a case of ileus duplex. The method is, however, a crude and almost barbarous expedient. It is true that it removes the obstruction completely, but in order to do so it robs the patient of much of the nourishment elaborated in the upper intestine and of most of the fluid taken by the mouth. This latter loss is the more important one. The effects of an enterostomy upon the patient's general condition may be compared to the effects of persistent vomiting. Even in cases where collapse and starvation are averted the miseries the patient has to endure from the escape of the intestinal juices upon the skin are so great that the operation should, I think, never be performed except as a last resort. The evils of enterostomy may be diminished considerably if there is a free passage into the large intestine below it, and in one of my cases which recovered I performed an ileo-cæcostomy combined with an enterostomy, but though this patient recovered his sufferings from dermatitis of the abdominal wall made me resolve to abandon the operation even when combined with an ileo-cæcostomy.

ILEUS DUPLEX FREQUENTLY MISTAKEN FOR GENERAL PERITONITIS.

In cases of pelvic suppuration when signs of intestinal paresis show themselves it is easy to jump to the conclusion that the paresis is due to the onset of a general peritonitis and that useful interference is limited to drainage of the peritoneal cavity. In the post-operative group of cases, as a rule drainage has already been provided, and a diagnosis of general peritonitis means the abandonment of any further effort to save the patient.

It is a remarkable fact that in the current edition of his work on "Intestinal Obstruction," which has been the guide of more than one generation of surgeons, Sir Frederick Treves has recanted his belief in the existence of ileus paralyticus. He says:

> The sole pathology of ileus paralyticus is summed up in the assumption that a portion of the bowel has become incapable of peristaltic movements, and as a result of this acute symptoms follow. I venture to think that ileus paralyticus, as described in the text-books and in the previous edition of this book, has no clinical existence.
>
> How often it is that the symptoms persist and rapid death follows the liberation of a coil of intestine strangulated by a band. Such death, however, is due to peritoneal infection or septicæmia, and not to ileus paralyticus. Those, however, who still claim that ileus paralyticus exists would maintain that the persistence of the symptoms and the final dissolution of the patient are due to the fact that the damaged coil of intestine remains paralysed.
>
> I have never met with an example of such a case as this in which a diffuse peritonitis was not met with after death.

Note that the basis for Sir Frederick Treves's disbelief in paralytic ileus is to be found in the last sentence I have quoted. He assumes that the general peritonitis found, as he truly says, in all cases at the necropsy is the sole and sufficient cause of death, and that cases of so-called "paralytic ileus" are really cases of general peritonitis. This false assumption, based on post-mortem pathology, is negatived by a study of the order of events in the living abdomen. As I have shown, observations in the operating theatre show marked evidence of obstruction before the appearance of any signs of general peritonitis. The general peritonitis found after death is a late result of the obstruction. This conclusion is amply borne out by the successful results of treatment directed towards the short-circuiting of the segment or segments of bowel which are presumed to be paralysed. On Sir Frederick Treves's hypothesis such treatment would be absolutely useless.

The evidence on this point derived from my cases of ileus duplex is fortified by a consideration of the results of short-circuiting operations in cases of obstruction by band. It has been my practice in such cases, wherever there was definite evidence of strangulation, and after the band had been divided, to short-circuit the affected loop by a lateral anastomosis. In cases thus treated I have found that recovery is the almost invariable rule.

The question is not merely one of academic interest. To label a case of ileus duplex as general peritonitis is to make a prophecy, not a diagnosis. In the course of a few days that prophecy will deplorably fulfil itself at the cost of the patient's life. I submit that upon the question at issue the views of Sir Frederick Treves may be rightly described as reactionary and dangerous in proportion to the distinction and authority of their author.

DIAGNOSIS OF ILEUS DUPLEX FROM GENERAL PERITONITIS.

Some of the ordinary criteria which distinguish general peritonitis from intestinal obstruction fail in the cases of ileus duplex, since, in addition to the obstruction, pelvic peritonitis is also present. Thus general peritonitis and ileus duplex present a close general resemblance. In both conditions there are general distension, vomiting, complete constipation, raised temperature and rapid pulse, with abdominal pain and distress and embarrassed abdominal respiration.

The points of difference between the two conditions, though few in number, are happily sufficient to distinguish them. In general peritonitis general rigidity of the anterior abdominal wall is the rule. In ileus duplex rigidity is absent or is present only in the hypogastric region. Moreover, the diffuse abdominal tenderness of the whole abdomen which characterises general peritonitis is not found in ileus duplex, nor does the pulse, however rapid, present the wavering quality of the peritonitic pulse.

When I speak of these differences you will understand that I refer to the earlier stages. Ileus duplex is no exception to the rule that intestinal obstruction ends in general peritonitis.

CONCLUSIONS.

Let me now attempt to sum up my conclusions. Peritonitis of the serous surface of the intestine, when it reaches a certain degree, is accompanied by complete paralysis of the involved segment of intestine. General peritonitis means general paralysis of the intestine, and is accordingly not amenable to surgical treatment. But if the peritonitis is partial, though unlimited by any adhesion barrier, certain segments only of the intestine are paralysed. If the paralysed segments can be thrown out of circuit by surgical measures recovery is in such cases possible and even likely. Unfortunately, in these cases the surgeon's hand has been paralysed by a facile assumption, based upon the general abdominal distension, that general peritonitis is present.

The position of the subject in 1903 is thus summed up by Douglas[3]:—

> Post-operative sepsis resulting in peritonitis produces paresis of the muscular wall of the intestine, and the resulting intestinal obstruction is the conspicuous symptom of the general peritonitis. In septic peritonitis, with conspicuous symptoms of obstruction, experience has taught us that secondary operations are so uniformly fatal that surgeons are discouraged in undertaking them. …… Enterostomy has been frequently done without avail.

This pessimistic view was held by Douglas, though he recognised that the paralysis might involve only small segments of bowel, because he wrongly assumed the presence of general peritonitis in such cases.

The observations I have made in the operating theatre and the successful results of my cases show conclusively that septic ileus of pelvic origin is not accompanied by general peritonitis when it first comes under observation, and that it is perfectly amenable to surgical treatment, subject to a clear recognition of the fact that two segments of the bowel are involved, and that accordingly two obstructions require to be circumvented.

You may complain that the name ileus duplex adds a new terror to medical nomenclature. It is the acknowledged privilege of the poet to give to airy nothing a local habitation and a name. I fail to see why the humble scientific observer, whose trammelled imagination must dance in tune with the facts of nature, may not assert at times the same right of fixing in language his comparatively dull realities. And in the present instance the name ileus duplex, whatever its defects, will, I believe, give such definition and precision to the condition I have described as to hasten its general recognition, and thus to save lives which might have been sacrificed.

[This lecture will appear in full, with case notes and illustrations, in an early number of the *British Journal of Surgery*.]

LITERARY INTELLIGENCE.—In view of the new issue of the British Pharmacopœia Messrs. Cassell and Co., Limited, will very shortly publish a new edition of "Materia Medica and Therapeutics," by Dr. J. Mitchell Bruce, assisted by Dr. W. J. Dilling, rearranged and rewritten to correspond thereto.

RADIOSCOPY WITH THE 3RD FRENCH ARMY.

BY LIEUTENANT-COLONEL A. W. MAYO-ROBSON, R.A.M.C., C.V.O., F.R.C.S. ENG.

With a Note by DR. HARET *and* DR. SCHLESINGER.

DURING a recent visit to France (kindly permitted by the Director-General of the Army Medical Department and at the request of the French Embassy) for the purpose of installing the Urgency Cases Hospital for the French wounded, I had the opportunity of seeing Dr. Haret, the radiologist to the 3rd Army, at work in one of the hospitals near the front. I think it may interest the readers of THE LANCET to know how excellent are the arrangements for carrying out radioscopy in the scattered hospitals near the front where it would be impracticable to instal a permanent apparatus.

A large covered motor ambulance carries, not only the operator and his assistant, but also a dynamo, which can be worked by the engine of the motor, and a transformer that can be used in those hospitals where there is an electric supply. It also carries a folding couch, stretchers, and all the apparatus necessary for radioscopy. This ambulance mobile regularly visits in turn the hospitals over a wide area, but if required for any special case it is available on giving short notice.

Dr. Haret told me that he had made as many as 50 radioscopic examinations with localisations in one morning and with each case is furnished a chart and drawing. It was most interesting to witness the celerity and skill with which the drawings were effected. In our hospitals in England radiography is more generally employed, and where a fixed apparatus is available and the necessary photographic chamber installed it presents many advantages over radioscopy, but in the crowded hospitals close to the battle line where 50 to 100 badly wounded cases may be brought in any morning, nothing but the most expeditious methods can be made use of, and here I have no hesitation in giving the preference to radioscopy.

In the Urgency Cases Hospital attached to the 3rd French Army we have an excellent X ray outfit, which was supplied by Messrs. Watson and Sons, of Great Portland-street, London, W., under the kind supervision of Sir James Mackenzie Davidson, and Mr. J. G. Everitt, our skilful radiographer, carries out the work with great celerity and accuracy. For instance, in the case of a recent shell wound of the shoulder with enormous swelling, I saw the X ray examination made and localisation of a large fragment of shrapnel casing effected by the method suggested by Sir James Mackenzie Davidson, and then a radiograph was made within a quarter of an hour, and half an hour later the fragment was removed by Mr. J. Cairns Forsyth, F.R.C.S., the "médecin-chef" of the hospital.

In the greater number of our cases we give the preference to radiography, but in simple cases radioscopy alone is employed.

Appended is an extract from a paper given to me by Dr. Haret which demonstrates his methods.

A Simple Method for the Localisation of Projectiles by Radioscopy, by DR. HARET *and* DR. SCHLESINGER.[1]

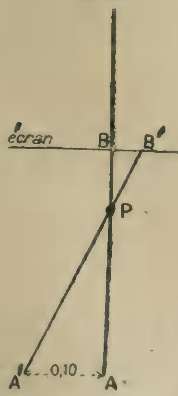
Localisation of projectiles becomes of more practical value as the means and methods are more accurately constructed, but all the technique has the defect of requiring radiographic reproductions, and of being too complicated. Much of the apparatus employed by civil radiologists in their consulting-rooms, where various instruments requiring delicate and long manipulation can be provided, is not practicable within the zone of a fighting army. For the last three months we have been working with a Gaiffe transport cart for radiology, midway between the front and the base—that is to say, in a district that has been largely devastated, and where we are reduced to find our own material and to use only such as presents no necessity for frequent repair. We have to work quickly and surely to give information to the surgeons, who have an enormous task before them and very little time to lose in fruitless investigations. The simplest means to fit to the circumstances are required, and we have consequently adopted for the localisation of projectiles a method which, while its construction can be managed with the means at our disposal, gives the surgeon accurate information by a simple consultation of the screen. The method is based on the principle of triangulation and has been adapted to radiology.

---

[1] Inspector-General Mignon has authorised the publication of this note.

We left Paris with a radiographic and radioscopic plant, but with the belief that the latter would prove the more valuable, a view that was quickly confirmed. At the front the localisation of projectiles by a plan on the screen direct, and a sketch, is the method of choice, and we have had the gratification of meeting with the approval of eminent surgeons who previously had given their preference to radiography. But to be useful and satisfactory radioscopy must be done in a special way. The sufferer reclines with the bulb below and the screen above—this is the best method of examination. In this way we are prepared for all eventualities in the region to be examined, whatever the state of the wounded, without having to modify the disposition of our apparatus and without loss of time. The bulb, furnished with a protective top and iris diaphragm, has a slide fixed on the edge of the table which permits every movement in the same horizontal plane. The screen, supported by another slide fixed on the opposite edge of the table, will move at the will of the radiologist above the patient. The patient can remain on the stretcher which is placed on the table, all useless and painful movement being thus avoided. We then make a radioscope of him from head to foot, stopping at the injured spots to construct a diagram on the screen, which replaces with advantage the perishable radiograph which takes so long to obtain. For we seek no fine details of bony structure, but only fractures, bullets, and pieces of shrapnel or shell, all of which things are perfectly visible on the screen wherever situated, when this is placed in the right position and the Chabaud bulb is properly manipulated. In order to be able to make every movement we arrange the radioscope by fixing the bulb on its support at a given distance from the surface of the table. We measure the distance of the focal point of the anticathode from the upper surface of this table—call it x cm. If now we place the horizontal screen in contact with the top of the table we shall mark on the screen that distance x in centimetres, and we shall adjust that scale, so that when the screen is fixed for an examination we read directly the distance AB exact from the focal point of the anticathode to the screen. This done, the use of a small "cleat" allows us in the darkness to displace by 10 cm. the bulb on the slide in the direction of the length of the table.

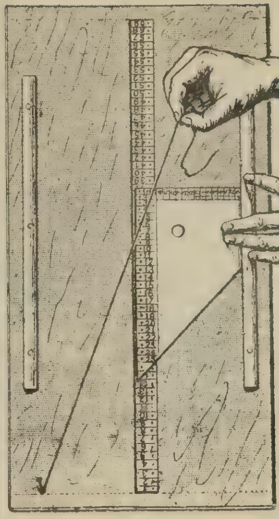
FIG. 1.



To localise the depth of a projectile during radioscopy, the screen is placed in contact with the skin over the part affected; the normal ray is made to pass by the projectile, and a shadow is obtained on the screen which is marked with a soft (*gras*) crayon as point B. (Fig. 1.) Then the bulb is moved the length of the slide for the distance A–A′, which we have fixed as 10 cm., and the projectile gives us a second image B′, which we also mark. We can measure the distance B–B′ of the two images of the projectile on the screen. The focal point of the anticathode in its two displacements and the two images of the projectile are in the same plane as the projectile.

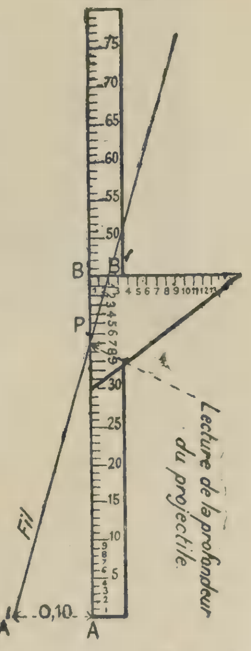
It is sufficient, then, for recognising the depth of the foreign body, to construct in the space the two triangles BPB′ and A′PA, which have two sides BP and PA in a straight line. The sides BB′ and AA′ are perpendicular to the straight line AB, and we know by simply reading them off the distances BB′ and AA′; if we join by a thread the points A′B′ we obtain on the line BA a point P at the apex of the two triangles, which is the exact point at which the projectile is situated; the distance BP, which can easily be read off, is the distance of the projectile from the skin.

FIG. 2.



For practical purposes we have devised the following plan. On a flat board (in this case the cover of the coil) is glued a dressmaker's metric tape measure of which one edge, the left, for example (Figs. 2 and 3), represents the line AB, and at A′ we fix a fine thread. We then take a set-square whose two sides containing the right angle are graduated in centimetres. To locate the situation of the projectile will then be very simple. For a thickness AB, we place the apex of the right angle of the square at the point B on the edge of the tape, corresponding to the number of centimetres indicated by the support of the screen. On the side BB′ of the square we note the figure found for the variation of the shadow of the projectile. If with the thread we then join A′B′ the thread cuts the line AB at a point P such that PB is the distance of the projectile from the skin.

FIG. 3.



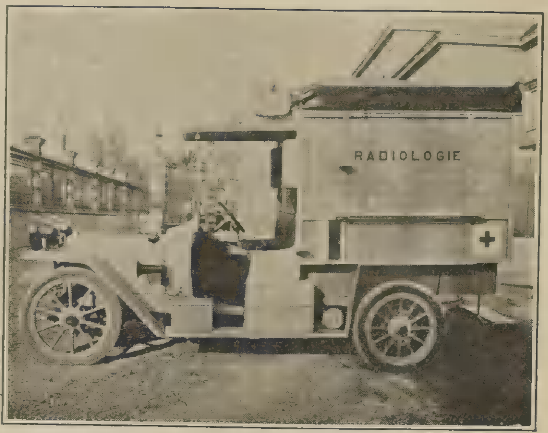
When for any reason we cannot apply the screen directly to the skin we perform the same operations by noting the difference of level between the place where the screen is applied and that whence the normal ray leaves the skin; we shall only have to diminish this distance on the figure found.

To sum up. The depth is determined by the following operations:—

1. Contact of the screen with the skin at the affected point.
2. Marking on the screen of the normal ray passing by the projectile.
3. Displacement of the bulb (10cm.) along the slide.
4. Marking of the new shadow of the projectile on the screen.
5. Measuring the distance between these two marks.
6. Reading off on the stem of the screen of the anticathode-screen distance.
7. Placing the apex of the right angle of the set-square at the figure corresponding to this distance on the tape-measure.
8. Stretching the thread from A to the figure of the edge BB′ of the square corresponding to the difference in centimetres of the two marks of the image.
9. Reading off on the vertical edge of the square of the figure at which the thread cuts this line; this gives the depth of the projectile from the skin.

This little device seems to us so simple that we make it known to those of our *confrères* who are deprived, as we are, of the fragile apparatus for localisation, but who can always find available a dressmaker's tape-measure, a piece of card to make a set-square from, and some thread.

FIG. 4.



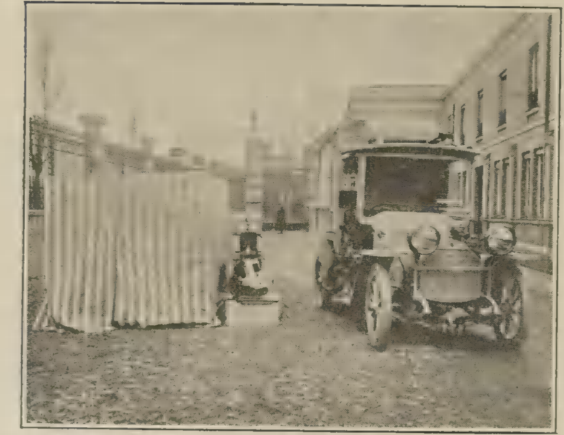
The "Radiologic Automobile."

Since the outbreak of war various designs have been brought out to meet the requirements of radiographers who are working in the field and clearing hospitals, but none seems more completely thought out than the "radiologic automobile," particulars of which have been kindly furnished me by the distinguished Présidente of the Croix Rouge Française.

Briefly, the outfit consists of a powerful modern motor chassis, upon which is mounted a van body divided into two compartments, the inner of which is a completely equipped photographic dark-room for developing X ray plates, the remainder of the car being most ingeniously fitted to carry the whole of the appliances and stores required. (Fig. 4.) Driven from the motor is a dynamo, which generates electricity, not only for lighting the interior and exterior of the car, but also for the X ray work itself. Included in the equipment carried on the car is a dark tent in which the actual examinations take place, and the necessary table on which the patient is placed, and, in fact, no detail seems to have been forgotten. (Figs. 5 and 6.)

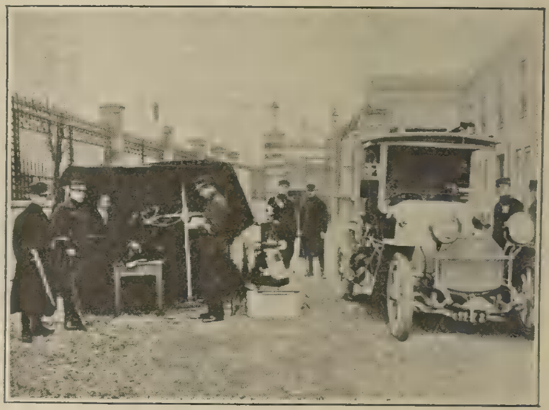
By means of one of these cars radioscopy or radiography can be performed anywhere, and as one outfit will serve a considerable number of hospitals great economy both in personnel and in money is effected. The cost of each complete installation is £850, and the Society of the Croix Rouge Française, 9, Knightsbridge, London, S.W., is anxious to name each car after a donor, whose name would be placed on it.

FIG. 5.



The automobile together with the dark tent in position.

FIG. 6.



Interior view of the dark tent during X ray examination.

The appended photographs, with permission to make use of them, have been kindly lent me by the Présidente of the Croix Rouge.

Basil-street, S.W.

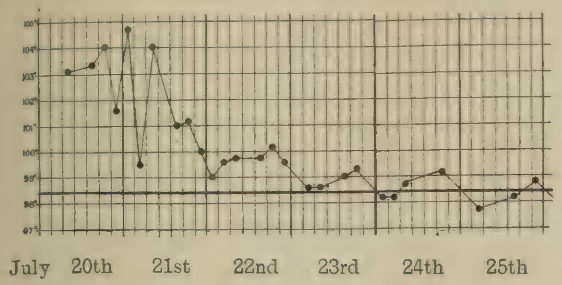
BLACKWATER FEVER.

BY R. W. BURKITT, F.R.C.S. IREL.

SEEING that "blackwater fever" is a disease with such a frightful mortality and that its treatment so far is not satisfactory, I consider that I am hardly justified in waiting for further cases before recording what seems to be the wonderful effect of neosalvarsan on it, as judged by these two cases (the only cases of this disease on which I have used it). The earlier case was in practically a hopeless condition and having rigors continuously when I gave him the neosalvarsan. The latter case was given neosalvarsan four hours after the blackwater appeared.

CASE 1.—The patient, aged 28, a professional white hunter, of temperate habits, had had "fever" on and off for a year. Quinine had been taken very irregularly. The spleen was a little enlarged. The laboratory report on the blood on July 20th, 1914, stated that no malarial parasites were present; some unknown bodies were seen; on the 28th no malarial parasites were seen. The urine report on the 20th stated that there were oxy- and methæmoglobin (very heavy), epithelial and granular casts, and an enormous quantity of débris. The progress of the case was as follows. On July 20th the patient had had no sleep. The urine was inky-black, acid, and HbO was present. Jaundice was deep and increasing. There was constant vomiting; the vomit was quite black. The spleen was just palpable. At 10 A.M. the temperature was 103·1° F. An intravenous injection of hypertonic solution (Rogers), 4 pints, was given, also pituitary extract. At 2 P.M. the temperature was 103·4°. Morphine, 1/4 grain, and hyoscine, 1/100 grain, were given. The vomiting stopped for six hours. At 6 P.M. rigors occurred; the temperature was 104°. $CaCl_2$, 30 grains, was given. At 10 P.M. the temperature was 101·6°. On the 21st the patient had had no sleep. HbO was present in the urine. At 2 A.M. there were rigors; the temperature was 104·7°, falling at 6 A.M. to 99·5°. At 10 A.M. there were again rigors; the temperature was 104°. Neosalvarsan, 0·9 grm., was given intravenously with 2 pints of saline. Two hours after the infusion the patient said that he felt cured; the vomiting ceased; the temperature was 101°. On the 22nd he had slept well. The urine contained a trace of HbO. The temperature was 100·1° at 6 P.M., and then ranged between 99·3° on the 23rd (6 P.M.) and 97·6° on the 25th (noon), being 98·6° on the 26th (8 P.M.). HbO was completely gone from the urine on the 23rd; on the 24th a trace of albumin was present, but no trace on the 25th. On the 24th the spleen was not palpable. The patient was given $CaCl_2$, 10 grains, twice daily, and an iron and arsenic tonic. He felt desperately weak but rapidly improved, and joined the Mounted Forces on August 8th.

Four-hour Chart.



CASE 2.—The patient, aged 50, married, was robust and of very temperate habits. He had had "blackwater" very badly 25 years ago, and migrated from Rhodesia to British East Africa to try to get rid of the effects of it, which kept him weak for five years. For the last four months he had been having "fever" on and off, and had been taking a good deal of quinine both by mouth and needle. During the past few weeks he had been getting very low. He had been trading for the last four months in Uganda and Kavarondo. The laboratory report on the blood, which was taken at 6 P.M. on Dec. 17th, 1914, just before the infusion of "914," showed that there were no parasites. On the 15th the patient had fever all day, feeling very ill. On the 16th he had had no sleep. He was retching all day and was very ill. The urine was acid and normal. At 10 A.M. the temperature was 100° F. He was given quinine, 10 grains, which was vomited. At 10 P.M. there was very high fever, but the temperature was not taken. He had quinine, 10 grains, which was retained. On the 17th he had had no sleep. He was retching all day and was very ill. In the afternoon he was jaundiced. At 2 P.M. there were very severe rigors; the temperature was not taken. The urine was as black as ink, very thick, and hard to pass. At 6 P.M. the temperature was 100°. He received an intravenous injection of neosalvarsan 0·9 grm., with two pints of saline; also morphine, 1/6 grain, and hyoscine, 1/100 grain. The laboratory report on the urine before the infusion stated that it contained an enormous quantity of oxyhæmoglobin, a certain amount of methæmoglobin, and an immense quantity of débris. At midnight the temperature was 98·4°. On the 18th he had slept well all through the night. The urine contained no HbO; there was a slight trace of albumin. The temperature was 97·6°. On the 19th the temperature was 97·6°. There was no trace of albumin in the urine. The patient was very weak, but was improving rapidly. $CaCl_2$, 10 grains twice daily, was given, and an iron and arsenic mixture. On the 23rd there were no parasites or pigment in the blood; there were poikilocytosis and polychromatophilia. The white cell count was: polymorphs 56·5 per cent., large mononuclears 13·5, lymphocytes 28, and eosinophiles 2 per cent.

Nairobi.

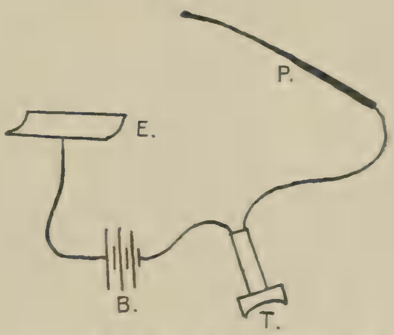
THE THEORY OF THE TELEPHONE PROBE.

BY R. G. CANTI, M.R.C.S. ENG., L.R.C.P. LOND.,
JUNIOR DEMONSTRATOR OF PATHOLOGY, ST. BARTHOLOMEW'S HOSPITAL, LONDON.

WHILST nothing but the simplest electrical phenomena are involved in the theory of the telephone probe, nevertheless an exact knowledge of it is necessary both that the operator may appreciate what is happening when the sounds reach his ears, and that the instrument may be so employed or modified that the most satisfactory results may be obtained.

The instrument was designed for the location of bullets and other foreign metallic matter within the human body. It consists essentially of a telephone receiver, one terminal of which is electrically connected with the skin of the patient by means of a flat electrode covered with wet cloth, whilst the other terminal is connected with a metallic probe. A dry battery may or may not be inserted in series with the telephone. The probe is introduced along the track of the bullet, and on contact being made with the latter a sound is produced in the telephone. (Fig. 1.)

FIG. 1.



Telephone probe. B, Battery. E, Electrode. P, Probe. T, Telephone.

r = Resistance of the tissues and telephone (a constant). r^1 = Resistance of the area of contact of the probe with the tissues. r^2 = Resistance of the area of contact of the bullet with the tissues. It is proportional to the area of the surface of the bullet, and therefore approximately to its size.

The intensity of the sound in a telephone is proportional to the current which is suddenly made to flow through it (within the limits for which the telephone is designed), and this is equal to the electromotive force divided by the resistance of the circuit. Or, $C = \frac{E}{R}$.

Now, suppose an attempt is made to locate a bullet in a patient. Directly the probe touches the tissues the resistance of the circuit is lowered from infinity to some high figure, and a current begins to flow. A click is heard in the telephone, but instantly the flow of current becomes even, and the sound ceases because the diaphragm of the telephone is again stationary. The current which caused the sound and which is now flowing is represented by $C = \frac{E}{r+r^1}$. The diaphragm, however, is slightly drawn in towards the magnets so that, if the probe is withdrawn from the wound, at the moment of breaking contact another click is heard which is caused by the return of the diaphragm to its original position. These sounds are always heard but must be ignored. When the probe is pushed further and further into the wound the quantity of r_1 is decreased, by reason of the increased area of contact of the surface of the probe with the tissues, and the flow of current through the telephone is therefore increased. This takes place very gradually, and the diaphragm is attracted evenly and slowly towards the magnets and no further sound is produced.

Now suppose the probe touches the bullet. There is now an additional path of flow open to the current—that is, from the bullet itself to the tissues—and its resistance, r^2, being added in parallel to r^1, the total resistance of the circuit is suddenly lowered, the current therefore is increased and a sound is heard. The current now flowing is represented by $C = \dfrac{E}{r + \dfrac{r^1 r^2}{r^1 + r^2}}$. (When two resistances are in parallel the total resistance is equal to their product divided by their sum.) If the area of the bullet is large the resistance r^2 will be low and the sound in the telephone loud, and conversely a small piece of metal will give rise to a comparatively weak sound. Should the contact between the probe and the bullet be now broken another sound will be audible in the telephone, and, further, an irregular grating sound will be heard as long as the probe is rubbed up against the bullet and the contact continually broken and remade.

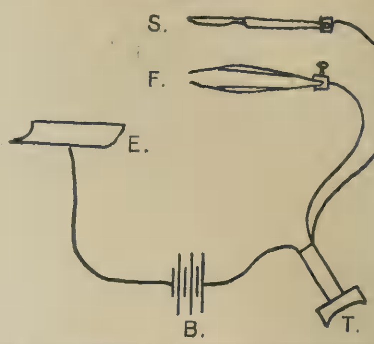
As regards the various factors which determine the efficiency of the apparatus, the following points should be noted.

1. *Sterilisation.*—All those portions of the instrument which come in contact with the tissues or the surgeon's hands should be capable of being easily detached for sterilisation and made of such material as will not deteriorate by boiling or other means employed for rendering them aseptic. As it is not necessary for the leads to be highly insulated, they may conveniently be made of bare flexible woven copper cord, which can be boiled along with the other instruments and has the advantage of not easily becoming entangled or kinking.

2. *Uses and limitations.*—Any good electrically conducting body, even if extremely small, is readily detected, and other solid material such as bone gives rise to no sounds whatever. Bullets, shrapnel, and other pieces of metal can thus be located where the simple probe fails to give any tactile sensation, or when the tactile sensation of bone may lead the operator astray. The instrument should comprise, besides probes of various sizes, one or more pairs of forceps for extracting bullets which can be rapidly and easily placed in the circuit in like manner to the probe. In the case of the forceps each limb should be separately connected with the lead, as otherwise sounds may be obtained by the rubbing together of the two halves of the forceps. Should other instruments be required for use at the same time they may be all connected up to the same lead by copper cords, placed in the instrument tray when not in use, and used if necessary more than one at a time; being all of the same potential they will not produce sounds in the telephone when they touch one another. Since a piece of metal the size of only a small fraction of a needle can so readily be detected, this method used with a scalpel and dissecting forceps connected in the circuit should prove very valuable for the difficult and tedious surgical operation of searching for a needle in the hand. (Fig. 2.)

It should be distinctly understood that the instrument is only of real value when the ordinary methods of detection are of no avail, and when the X ray, if obtainable, is deceptive.

Fig. 2.



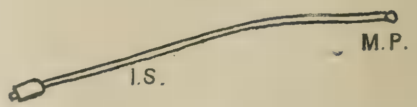
Same as Fig. 1 with scalpel and forceps in place of probe. S, Scalpel. F, Forceps.

3. *The telephone.*—This part of the instrument should be highly sensitive to the slightest variations in current, and should be by a reliable maker, as an inferior article gives poor results. A pair of telephone receivers should be used connected together with a head-piece, and having a total resistance somewhere between 100 and 1000 ohms.

4. *The source of the current.*—Many telephone probes are not supplied with a battery, but are designed to be used with the small current generated at the area of contact of the body with the electrode, which is sometimes made of metal and sometimes of carbon. The potential of this skin current is only a small fraction of a volt. Much louder sounds are obtained, and much smaller pieces of metal can be located by employing a few dry cells in series with the telephone. Two batteries as used in small flash-lamps and having a potential of 6 volts are sufficient. The reason why a higher voltage is more advantageous is that, all other conditions being the same, there is a greater difference in the amount of current flowing through the telephone before and after contact with the bullet, and therefore louder sounds are obtained. By referring to the formula $C = \dfrac{E}{R}$ it follows that, when the probe touches the bullet and the value R is suddenly lowered, the higher the value of E, the greater will be the current made to flow suddenly through the telephone.

5. *The probe.*—Finally the instrument can be rendered markedly more efficient if an "insulated probe" be used in place of the ordinary bare probe.

Fig. 3.



The probe. I.S., Insulated shaft. M.P., Metallic point.

(Fig. 3.) By again referring to $C = \dfrac{E}{r+r_1}$ (before contact with the bullet). $C = \dfrac{E}{r + \dfrac{r_1 r_2}{r_1 + r_2}}$ (after contact), it is seen that a much greater increment of current will result if the resistance r_1 is high. And as r_1 is the resistance between the probe and the tissues, the area of the former coming into contact with the latter should be reduced to a minimum. In order to achieve this the probe should be made of silver or some other non-corrodible substance, with a small knob at the end, and with the shaft covered with white gum-elastic material which will not deteriorate by the ordinary methods of sterilisation. This insulated probe is further advantageous in that instruments not connected in the circuit may be passed along it without creating sounds in the telephone.

N.B.—Since the above description was written, Mr. Gillies has afforded the benefit of his experience by the following valuable suggestion. The lead usually connected with the probe is connected to an electrode secured on to the operator's arm, whilst the probe is held in the hand and used without any metallic connexion with the rest of the apparatus. By this means the current is made to flow through the body of the operator in addition to its usual course. This it will do without appreciable loss of efficiency, the only points to be observed being that the hand must be wet and must not be covered with a rubber glove. The advantages are that instruments do not have to be attached and detached continually, and that any instrument can be used which has not been specially made to fit the apparatus.

THE SIGNIFICANCE OF NUCLEAR VARIATIONS OF NEUTROPHILE LEUCOCYTES (ARNETH COUNTS) IN WEST AFRICA.

By J. W. SCOTT MACFIE, M.A., M.B. CANTAB.,
WEST AFRICAN MEDICAL STAFF.

RECENT investigations into the effect on white men of residence in a tropical climate have shown that a definite change may be observed in the blood—namely, a "shift to the left" of the Arneth count. Chamberlain and Vedder (1911) made Arneth counts on 72 American soldiers in the Philippines, and for comparison on 50 Filipinos. They concluded that "the average Arneth picture showed a marked shift to the left in the case of Filipinos and a slight shift in the same direction for Americans resident more than one year in the Philippines." More recently Breinl and Priestley (1914) performed Arneth counts on 150 school children living in tropical Queensland, and found that they showed "a marked shift to the left, the Arneth index being 74·5 as compared to 40 for normal individuals (Arneth) in Europe," and they expressed the opinion that this change was "due to the effect of a tropical climate upon the white race living in the tropics."

The exact significance of this "shift to the left" in the Arneth count is not yet determined with certainty, but is by most authors considered to be "the expression of a lowered resistance of the body to infection." Arneth himself believed the neutrophiles of his Classes I. and II. to be immature leucocytes. Breinl and Priestley, however, dissent from this view, pointing out that according to Busse (1910), and to some experiments of their own, no difference in the phagocytic power of the neutrophile leucocytes belonging to the different classes distinguished by Arneth could be demonstrated *in vitro*. These authors express the opinion that the shift is the outcome of purely climatic influences, and point out that it becomes more pronounced after a prolonged residence. The phenomenon is at any rate an extremely interesting one in view of the tendency at the present time to deny that climate in itself affects Europeans in the tropics.

A number of Arneth counts were performed at Accra during the latter months of 1914 on sick and healthy Europeans and natives. The investigations are still being carried on, and a complete account of the results obtained will be delayed until later. It may, however, be stated at once that malaria infections appeared to have a marked effect on the Arneth blood picture. In a number of cases of malarial fever in which there was a heavy infection with the subtertian parasite (P. falciparum) there was found to be a well-marked "shift to the left" of the Arneth count, and this phenomenon persisted after all parasites had vanished from the blood, and after the patients had recovered from the attacks. Details of only one case need be given here (see Table). This was a fatal case of malaria in which 47·65 per cent. of the red blood corpuscles were invaded by parasites. On performing an Arneth count it was found that no less than 95·5 per cent. of the neutrophile leucocytes belonged to the Classes I. and II. The great majority of the neutrophile leucocytes had sickle-shaped nuclei.

Table showing Arneth Count in an Exceptionally Intense Malarial Infection (P. falciparum).

—	Arneth classification per cent.					Index.
	I.	II.	III.	IV.	V.	
Normal in Europe (Arneth) ...	5·0	35·0	41·0	17·0	2·0	40·0
Intense malarial fever	78·0	17·5	4·0	0·5	0·0	95·5

In this case the neutrophile leucocytes had ingested a large number of malaria parasites which were clearly visible in their cytoplasm. It was therefore possible, using the number of these as an index, to gauge the phagocytic power of the various cells *in vivo*. As, however, the leucocytes of Classes I. and II. predominated to such a marked extent, it was difficult to find a sufficient number of those belonging to the higher classes for comparison. It was nevertheless noted that the leucocytes in which the ingested parasites were most numerous were almost always those of Class I., some of which contained as many as 30 or 40 crowded into their cytoplasm. This observation would seem to indicate that there is at least no reduction of the phagocytic activity in the neutrophile leucocytes of Arneth's Class I. The observation also supports the view of Breinl and Priestley that "the Arneth picture is an expression of the functional activity of the leucopoietic system"; for if their hypothesis were true, it would be in such diseases as subtertian malaria, that profoundly affect the spleen and the bone marrow, that one might expect to find a marked "shift to the left" indicating a morbid activity of these tissues.

It is not my intention to discuss the matter further at present, as I hope to return to the subject at a later date; but it may be pointed out that in interpreting the significance of a "shift to the left" in the Arneth blood counts in West Africa the bearing of malarial infections, both recent and more remote, will have to be carefully considered.

EXTRA-UTERINE GESTATION SIMULATING APPENDICITIS.

By E. Mansel Sympson, M.A., M.D. Cantab., M.R.C.S. Eng.,
MAJOR, R.A.M.C. (T.F.); HONORARY SURGEON, LINCOLN COUNTY HOSPITAL.

On April 18th, 1914, a married woman, aged 22 years, was admitted into the County Hospital, Lincoln, under my care, suffering apparently from an attack of appendicitis. The following history was given. The first serious attack of pain in the right side of the abdomen came on on April 13th and continued off and on till another more serious attack on the evening of the 17th, accompanied by vomiting. The patient had had two children, the last of whom was born on Dec. 1st, 1913. A menstrual period had ceased at the beginning of April, but some loss appeared on April 13th and continued till the day of operation. There was tenderness in the right iliac fossa on deep palpation, but no definite swelling, and the abdomen moved freely on respiration. The temperature was normal; the tongue only slightly coated. As she was menstruating and the pain seemed to be leaving her, I decided to wait a few days before operating.

On April 29th I made the usual incision for appendicectomy, and on opening the peritoneum found that part of the abdomen occupied with blood clot and some fresh blood. This at once suggested extra-uterine pregnancy, so I closed the wound, opened the abdomen in the middle line, washed out the hæmorrhage, found, tied, and cut off the right ovary and tube, of which the outer third was much enlarged, and in which the gestation sac was situated. This had burst intraperitoneally, and was probably, judging also from the patient's history, of about 11 to 12 weeks' growth. The uterus was somewhat enlarged, and slight hæmorrhage had occurred through the cervix.

The after-history is unimportant, as the patient made an excellent recovery, and was discharged from hospital on May 19th, 1914.

A very similar case came under the care of my colleague, Major D. J. G. Watkin, at the hospital, almost simultaneously.

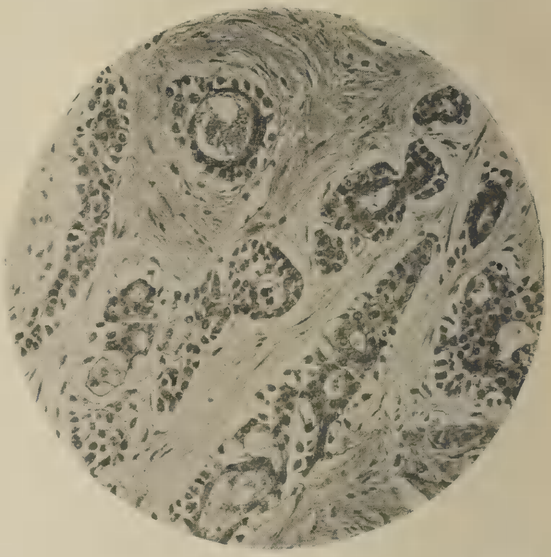
Lincoln.

NOTE ON A TUMOUR OF THE MAXILLARY ANTRUM.

By H. N. Taylor, M.A. Cantab., M.D. Dub., F.R.C.S. Edin.,
MAJOR, R.A.M.C. (T.F.); SURGEON, EBBW VALE HOSPITAL, MONMOUTHSHIRE.

On Feb. 15th last Mrs. ——, aged 34 years, came to the hospital as an out-patient, complaining of pain "in the right side of the face." On examination there were pain and tenderness over the right cheek, with apparently some little bulging of the affected side, with symptoms of neuralgia of the right infra-orbital nerve. There was no nasal discharge, no obstruction of the nasal duct, and no exophthalmos. The teeth had been extracted some months previously with an idea of relieving the pain, but the symptoms had become more pronounced rather than improved. Internally there was a distinct prominence of the antral wall over the alveolus, with a sensation that the wall of the cavity was "thinned out." On transillumination the right side was found to be quite opaque, in marked distinction to the rosy glow transmitted through the left maxillary region.

I admitted the patient to the hospital and subsequently opened somewhat freely the antrum over the alveolus. A hard, indistinctly lobulated tumour presented itself, which was, with some difficulty, delivered through the opening. It proved to be a dense greyish-white conical growth about two and a half inches long with a base of about an inch, one edge of which was partly attached to a small bony ridge in the antral cavity, which I snipped off to complete the removal. On cutting into the growth the appearance suggested a fibroma with a few small hæmorrhages into the substance of it. I, however, sent a piece of the growth to the Clinical Research Society, and append the society's report and a micro-photograph :—



This is a very unusual form of growth, and its nature is quite obscure. It is largely composed of tough, fibrous tissue, but all around near the surface there are masses of gland-like elements and lymphatics with proliferating epithelium. This portion suggests an endotheliomatous growth not unlike some forms of parotid endothelioma, and if this is the true nature of the tumour, then the bulk of it must represent a fibrous transformation. There is no normal tissue present, so that we cannot say whether there is any infiltration, but the appearances do not suggest malignancy. The magnification is × 200.

The cavity rapidly filled up and the patient left the hospital in a fortnight very satisfied that the constant pain she had suffered for over 12 months was now completely—and I hope permanently—removed.

Ebbw Vale, Mon.

Donations and Bequests.—Subject to certain life interests the late Mr. Thomas Ballington, of Edgbaston, Birmingham, has left by will £2000 each to five Birmingham hospitals, £500 to the Birmingham General Dispensary, and smaller sums to 10 other medical charities in Birmingham.—By the will of the late Mr. A. Sutton, of West Bromwich, the Eye Department of the West Bromwich District Hospital and the Ackrill Nursing Home will each receive £1000.—The St. Albans Hospital and the West Herts Hospital will receive £2000 and £1000 respectively under the will of the late Mr. Charles Woollam.

ROYAL SOCIETY OF MEDICINE.

SECTION OF ANÆSTHETICS.

The Influence of Preliminary Narcotics on General Anæsthesia.

A MEETING of this section was held on March 5th, Dr. HAROLD LOW, the President, being in the chair.

Dr. J. BLUMFELD, after referring to the previous discussion on this subject four years ago, when the procedure was novel and very diverse views were put forward as to its value, said that further experience had enabled us to exercise discrimination and to declare that there were cases where this method was of the greatest value, and others where it should not be employed. The first point which he wished to raise was the routine use of preliminary narcotics. His own view was that none of these drugs should be employed as a routine except atropine. It was not a reasonable course of action to prescribe morphia and scopolamine for patients whom they had not seen beforehand, or unless at least they had satisfied themselves that in every probability these drugs would not upset the patient. It was also necessary that the patient should not have to walk or be disturbed before the operation. It was particularly in hospital practice that he objected to their routine use, because it often happened that the experienced anæsthetist who was expected did not actually give the anæsthetic, which then fell to the lot of an inexperienced junior, who would not have had a preliminary injection given had he known he was to be the anæsthetist. These remarks did not apply to atropine which rendered convenient the free use of open ether. Again, the case might turn out to be one in which deep chloroform anæsthesia was indicated, and he thought that was not a method to be safely practised. The advantages to be derived from the use of these narcotic drugs were, firstly, a quiet induction with a patient indifferent or asleep; secondly, a diminished consumption of anæsthetic; and, thirdly, diminution or absence of all deleterious after-effects. Scopolamine alone, or combined with morphine, was more potent and gave great help in highly nervous individuals. Yet there were cases in which these drugs caused nausea or excitement. Again, these drugs, in his opinion, prolonged induction and particularly delayed complete muscular relaxation. With regard to after-effects, the balance of evidence was in favour of the good results from scopolamine with or without morphia. Sickness was sometimes delayed; more often it did not occur or was slight. He preferred to use these drugs in highly nervous individuals, in all long nose and throat cases, and in all very muscular, plethoric, or alcoholic individuals. In the nose and throat cases a light degree of narcosis was possible with unabolished cough reflexes.

Sir FREDERIC HEWITT said that he had a high opinion of the use of preliminary narcotics, provided care and discretion were exercised. Whenever practicable the anæsthetist should see his patient some time before the operation. In certain special cases a trial administration might be made a day or two before the operation. He had no doubt as to the general advantages of the plan of preliminary narcotisation. Atropine was very valuable in preventing nasal or oral secretions. He had never seen any contra-indications to its use. He had of late become rather shy of scopolamine except in cases where definite pre-anæsthetic stupor was indicated. Provided there were no contra-indications, he was inclined to use morphine and atropine, ¼ gr. for adult males, 1/6 gr. for women, with 1/150 gr. of atropine, before practically every operation. He preferred freshly prepared solutions to tabloids. Morphine should not be given to patients suffering from respiratory difficulties, nor in throat, nose, and mouth operations liable to be attended by hæmorrhage, unless a light anæsthesia was maintained. He did not think the profession fully realised the importance of a rapid return of the reflexes after these operations. He agreed that the sleep-like breathing of morphinised patients sometimes prolonged the administration. He did not remember any case in which marked slowing of breathing had taken place during full anæsthesia.

Dr. W. H. TATE was entirely in favour of the preliminary use of narcotics, either morphine and atropine alone or combined with hyoscine. Hyoscine was not advisable in old and feeble patients. In his experience, which embraced operations chiefly on the lower abdomen, there had been no difficulty in obtaining satisfactory relaxation. In many cases the patient's senses were partly dulled, in some there was entire freedom from nervous tension. It was quite an exception for any troublesome sickness to occur.

Dr. JANE TURNBULL agreed with Dr. Blumfeld that the use of atropine alone was very satisfactory, and the use of morphine and atropine in operations on the nasal passages was of great value.

Dr. Z. MENNELL completely agreed with Dr. Blumfeld's conclusions. He thought it must be generally allowed that scopolamine sometimes made difficult complete relaxation in high abdominal cases.

Mr. H. E. G. BOYLE thought that the discussion had emphasised one point—viz., that anæsthetists ought to see their patients a day or two before the operation. It was obviously wrong to prescribe a routine dose of any narcotic without first seeing the patient. It was an important point that patient and anæsthetist should not be strangers on the morning of operation. He had found recently that a fairly strong dose of morphine and scopolamine with atropine had been of benefit during the induction of soldiers who, although outwardly calm, were one and all nervous. A great drawback was the intense thirst and dryness of the mouth produced.

Dr. G. A. BARTON had practically adopted the administration of narcotics before anæsthesia as a routine method during the last three years. He thought solutions were better than tabloids. Owing to the depression of the respiratory centre induction was slower than usual unless, as in his own practice, ethyl chloride were added to the chloroform, or ether or combinations of these agents used for induction. Struggling was less marked. The best results during anæsthesia were obtained by a full dose of morphia and scopolamine, say ¼ gr. and 1/100 gr. as a routine, with more morphia for strong big men, with the subsequent use of the minimal dosage of open ether. He liked to keep a brisk corneal reflex. With this form of narcosis shock practically never occurred. He had practically given up strychnine or pituitrin saline infusion, and artificial respiration. He deprecated the use of chloroform with narcotics. After referring to the dangers of chloroform and the work of Dr. A. G. Levy he said that following the use of alkaloids and open ether the patient generally slept comfortably, and was rarely troubled with vomiting or other discomforts. One occasionally came across cases of idiosyncrasy to morphine and scopolamine.

Dr. F. E. SHIPWAY said he was entirely in favour of preliminary narcotisation whenever possible. It was a kindness to the patient and a help to the anæsthetist. He preferred morphine and atropine for the majority of cases, with the addition of scopolamine for very nervous patients. Scopolamine sometimes made induction slow, and delayed the onset of complete muscular relaxation in operations upon the upper abdomen. Small doses of morphine with atropine were an advantage in operations upon the nose, throat, and mouth. As regards after-results, patients made a better recovery if narcotics had been given. He thought that flatulence was not, on the whole, increased. Chloretone could be substituted for morphine in selected cases; he had found it useful sometimes for patients who had on previous occasions been much troubled by vomiting.

The PRESIDENT said that most anæsthetists were now able to give an expert opinion as to the advisability of using narcotic drugs as a preliminary to anæsthesia. He quite agreed with Dr. Blumfeld that their routine use in hospital practice was not advisable. In unskilled hands their use was not free from risk. At St. Thomas's Hospital the resident staff were not allowed to use narcotic drugs. Deep chloroform anæsthesia should never be induced subsequent to their administration. He had never seen any ill effects from the use of atropine. He was in favour of the use of morphine and atropine in skilled hands and in selected cases, but he was not so certain of scopolamine, the action of which was not always to be depended upon. Following the use of morphine and atropine the patient was asleep or in a state of quietude, less anæsthetic was required, and post-anæsthetic sickness was rare. He hoped that if he had ever to undergo an operation he might be given a preliminary narcotic injection.

ROYAL ACADEMY OF MEDICINE IN IRELAND.

SECTION OF STATE MEDICINE.

The Recent Outbreak of Cerebro-spinal Meningitis in the Dublin Military District.

A MEETING of this section was held on April 16th, Dr. T. P. C. KIRKPATRICK, the President, being in the chair.

Dr. G. E. NESBITT gave an account of the recent outbreak of cerebro-spinal meningitis in Ireland. Eighty-nine cases had been notified to the Local Government Board since Jan. 28th last, of which 30 had occurred in the Dublin Military District, with which his remarks were chiefly concerned. The mortality rate, so far as his figures were available, was 50 per cent. The features of the outbreak were in accordance with general experience. No source of infection could be ascertained in the majority, and no two cases occurred in the same building. He emphasised the importance of early diagnosis, if necessary by lumbar puncture, and pointed out that in Ireland in civil practice too little attention was paid to the examination of contacts. In military practice the greatest importance was attached to this matter, and careful search was made for carriers. He sketched briefly the routine method of examination and the steps employed to limit the extension of the disease.

Professor E. J. MCWEENEY said the disease was one that had an intense attraction for the pathologist. He suggested as an explanation of this disease that the cases of cerebro-spinal meningitis that occur only constitute a small minority of the cases of an epidemic catarrhal affection; the mystery of the disease would then disappear, leaving a widespread catarrhal affection all over the country, with here and there a meningitic complication. How the diplococcus got from the pharynx into the cranial cavity had been under investigation for a long time, and light had recently been thrown on this by the discovery of the meningococcus in the blood. He recommended that in a case of suspected meningitis 10 c.c. of blood should be removed from the arm for examination. He also impressed upon clinicians the necessity for doing lumbar puncture early, and said it would be found to be a matter of extreme simplicity if the proper needle was used. He pointed out that one of the leading features of this bacillus was its extraordinary tendency to die off, and he considered that this might be due to the fulminating character of the micro-organism, and it was just possible that the fulminating cases were the ones in which there was difficulty experienced in getting the organisms.

Sir JOHN MOORE compared the statistics of cerebro-spinal fever with those of whooping-cough. In the 13 weeks ending April 3rd the deaths from the latter disease numbered 98, as compared with 8 from cerebro-spinal fever, and notwithstanding the enormous toll exacted by whooping-cough amongst infants it was not a notifiable disease. He was glad that Dr. Nesbitt did not allude to that most misleading term "spotted fever," and he would like to know if any of his cases were marked by purpuric eruption.

Dr. J. A. MATSON mentioned two cases of the disease which came under his care. One of them was so spotted that he thought at first it was a case of typhus fever, and the other showed no spots. In both cases the patients recovered.

Dr. J. MARSHALL DAY said six of the cases came under his care. Two of them came from outside the city, and were therefore not notifiable in the Dublin registration area. All the patients died with one exception. All patients admitted to hospital were given spinal injections, but he had very little success with serum except in the one case. Referring to cases of a prolonged type, he recalled the case of a child in which he tried injections of fibrolysin, and the patient rapidly improved and was discharged, but came back a fortnight afterwards stone deaf. In another case a child was nearly blind; fibrolysin was tried and the sight came back. Although full investigation was made in two of the cases admitted, no connexion with any previous cases could be found.

The rest of the meeting was occupied by a paper by Sir JOHN MOORE on the exploitation of medical men in the matter of medical certificates. We notice the communication elsewhere.

Reviews and Notices of Books.

The Minor Horrors of War.

By A. E. SHIPLEY, Sc.D., F.R.S., Master of Christ's College, Cambridge. London: Smith, Elder, and Co. 1915. Pp. 166. Price 1*s*. 6*d*.

THIS little book can be recommended, not only to the medical staff of the Expeditionary Force, but to all who are living in camp, bivouacking, travelling in hot countries, or are in any way deprived of the means of securing an ideal cleanliness of person. It tells all that anyone can need, and more than most people desire, to know about insect plagues and how to circumvent them; and, secondly, it has been, as the author admits, "written in a certain spirit of gaiety," and thus makes entertaining the study of a subject in itself rather repulsive.

Beginning with the louse, the author mentions that typhus fever has been proved to be spread by P. vestimenti in a recent outbreak in Ireland; both this species and P. capitis spread relapsing fever. The first rule in dealing with the parasite is to search the person as often as possible for signs of its presence, and then to apply petrol, paraffin, or other insecticide, and to examine and treat the clothing. The wearing of sulphur in calico bags, about 2 inches square, next the skin is also recommended. In regard to the bed-bug Professor C. J. Martin's statement is quoted, that there is really no evidence to incriminate this insect in the case of either typhus or relapsing fever, and no epidemiological reason for supposing that infection by its means takes place to any extent in nature. Fleas and lice suck blood several times a day, but bugs "show no disposition to feed for a day or two after a full meal; their dejections were found to be fully digested, almost free from protein, and consisted mostly of alkaline hæmatin." It is pointed out that the wooden huts which have been erected to so great an extent recently will afford convenient quarters for bugs. Against them fumigation with sulphur is recommended: it is much less expensive and less dangerous than using hydrocyanic acid gas; also the "flares" used by painters for burning off paint have been found to exterminate them from match-boarding and wainscoting. The establishment of the fact of the conveyance of plague by means of fleas has removed them "out of the category of those animals which it is indelicate to discuss," though, compared with the company to whom Dr. Shipley has already introduced his readers, the flea is socially unobjectionable. The common idea that the chief occupation of monkeys (at any rate in the Zoological Gardens) is the chase of the flea is declared to be erroneous; we are told that "no fleas have been found truly parasitic on monkeys," although usually in confinement a human flea attacks them, which implies that it is the monkey that has ground for complaint. The relation of fleas to plague is described, and the efficacy of cowdung floors for keeping them away is vouched for.

The ingenious and important researches of Lieutenant-Colonel W. W. O. Beveridge, R.A.M.C., and Mr. Durrant on the moth which infests army biscuits (Ephestia Kühniella) are summarised. The best way of getting rid of the pest is thorough fumigation of the flour mill premises with carbon bisulphide, but it is judiciously recommended that "as this substance is not only poisonous but inflammable, it is well to get a chemist to undertake the proceeding, and also to notify the insurance company." The pathetic story is told of the troops in Egypt in 1801 whose biscuits were so full of worms "that the men could only eat them in the dark." The discussion of the pathogenic activities of flies takes two chapters, and this without entering on the subject of malaria at all. Mites, ticks, and leeches are fully illustrated, and their many activities described in detail, with apt quotations and illustrations. These chapters first appeared in the columns of the *British Medical Journal;* they are well worth reproduction in their present form.

There are rather more misprints than would be expected—"von Hinderberg" might be passed, but "*Hydrophylus*" hardly. We have to thank Dr. Shipley for a most useful and entertaining book.

Students' Text-book of Hygiene.

By W. JAMES WILSON, M.D., D.Sc. Belf., D.P.H. Cantab. London: William Heinemann. 1915. Pp. 270. Price 8*s*. 6*d*. net.

THIS text-book, which Dr. Wilson has based on courses of lectures given during the past seven years to the hygiene class of the Queen's University, Belfast, forms a handy little volume, well printed, light to hold, and essentially readable. It succeeds, we think, in going over the enormous territory which is now occupied by "hygiene" in a way well calculated to interest the student; and without burdening him overmuch with the laws, forms, and official schemes necessary for the practical administrator it gives a large amount of essential information. Reservations have occasionally to be made—for example, to the statements that on an average a quarter of a ton of refuse is produced per head of population per year; that carburetted water gas contains 30 per cent. of carbon monoxide; that good cheese usually contains three times as much fat as the same weight of meat, or that water "reservoirs should hold at least 150 days supply." But if in practice things are not so simple and straightforward as they may be represented in the lecture room, the student is none the worse for being put somewhere there or thereabouts on such questions.

It is evident that Dr. Wilson's book is the product of wide reading, and his short accounts of different matters are usually in very good perspective. Perhaps an exception may be made in respect of the chapter on infectious diseases, which seems to give too little consideration to their natural history, their occurrence as epidemics, and the degree to which they attack race, sex, and age. Dr. Wilson draws freely on recent contributions to knowledge in the matter of spread of infection by carrier cases, but we think that the present-day student, besides being taught the large number of difficulties which the carrier has removed, might well be given a caution as to the new difficulties which are thus created. Gilbert's saying that when everyone is somebody no one is anybody deserves to be remembered when the carrier is pressed overmuch in explanation of epidemic diseases.

MISCELLANEOUS VOLUMES.

THE public owes a debt of gratitude to the Trustees of the British Museum for their many excellent and cheap handbooks to the collections of specimens exhibited in their galleries. Another handbook to the series has just been added which explains in a succinct and admirable way the meaning of the interest which attaches to the discovery of the Piltdown skull, to which there have been many references in the pages of THE LANCET. *A Guide to the Fossil Remains of Man in the Department of Geology and Palæontology in the British Museum* (Natural History) is a little book of 30 pages which summarises the evolutionary theory of man through the primates and describes the Piltdown man, so far as we are able to conceive him, from the skull which was discovered by Mr. Charles Dawson in 1912. The reproductions of photographs of the fragments of the skull and the drawings of teeth, together with flints found in the river gravel at Piltdown, are admirably done, and the handbook should certainly find a place among the literature of the subject. The Guide can be obtained, price 4*d*., in London, at the Museum (South Kensington), of Messrs. B. Quaritch, and of Messrs. Dulau and Co.; in Birmingham, from the Midland Educational Company; in Manchester, from Messrs. Sherrat and Hughes; and in Glasgow, from the Grant Educational Company.

The war naturally continues to claim wide attention, and the output of books relating thereto is extensive. In *Thou Art the Man: the Story of a Great Crime* (London: T. Werner Laurie, Limited. 1915. Pp. 94. Price 1*s*. net), by Mr. SIDNEY DARK, the author endeavours to help those who do not read Blue-books to form a clear understanding as to why the war began, what exactly are the forces against which the Allies are struggling, and why we must fight until those forces are subdued. He tells the story of the German Empire and the atavism which now characterises it to impress the public with the fact that Prussianised Germany desires to force other peoples to be German whether they will or no.——In *How Belgium Saved Europe*, by CHARLES SAROLEA, with a preface by Count GOBLET D'ALVIELLA, Belgian Secretary of State, and a map of Belgium (London: William Heinemann. 1915. Pp. 226. Price 2*s*.), the author, who is the Belgian Consul in Edinburgh, has written a very readable book which, like the preceding, throws a great deal of light on Germany of to-day as distinguished from Germany of Lessing and Goethe, though its primary object is to present a record of Belgium's sufferings as a consequence of her rigid adhesion to duty. A chapter is devoted to a character sketch of King Albert, one of the most popular monarchs of to-day, while others give in well-chosen words a vivid picture of Belgium's martyrdom.——In *Nietzsche: the Preacher of War*, translated by HELEN ZIMMERN (London and Edinburgh: T. N. Foulis. Pp. 268. Price 1*s*. net), we are presented with views on religion, on virtue, on what is noble, and so on, but the views are not in accord with accepted principles of right and wrong. As a specimen of the teaching of Nietzsche the book is interesting.

JOURNALS AND MAGAZINES.

The Military Surgeon (*Chicago*).—In the March number Colonel H. P. Birmingham, Medical Corps, United States Army, Chief Surgeon of the United States Expeditionary Force in Vera Cruz, April 24th to Nov. 23rd, 1914, reports on the sanitary work done during the occupation. The sanitary problem was grave as there was small-pox in the city and the population was unvaccinated, flies were a "terrific" pest from want of scavenging, cerebro-spinal meningitis had been recently prevalent, the time for malaria was approaching, yellow fellow had indeed been mastered during the preceding five years, still there was tuberculosis (very prevalent) to beware of. Immediately on landing houses occupied as barracks were thoroughly cleaned and disinfected, company kitchens and messes were promptly screened, and 3-grain doses of sulphate of quinine were issued daily to the force. The army was protected against small-pox and typhoid fever, so these diseases caused no anxiety to the medical officers. Water carriage of excreta was generally available, but where necessary latrines were dug, fitted with fly-proof covers and burnt out (with 7½ lb. hay and 1 gallon crude oil) twice daily. Manure and rubbish were sent to the destructors; picket lines were kept clean and burnt over every week. Baths were installed, the disposal of waste waters was carefully watched, and 69,000 gallons of crude oil were used for oiling stagnant water, while in addition 61 miles of drainage ditches were dug. The hospitals and sanitary administration of Vera Cruz were taken over, the port and quarantine by that most capable body, the United States Public Health Service, the rest by the army. A small corps of specialist sanitarians was sent up from the canal zone, and many of the Mexican staff were induced to remain, and did well. 46,420 vaccinations were done. The city was inspected throughout every five days, and foods were all regularly examined. Deaths from malaria fell to one-tenth of the average. Venereal disease was limited by the issue of prophylactic packets to civilians as well to troops, and by the weekly examination of all suspected women, and the instructive figures are recorded that of registered women 25 per cent., and of clandestine prostitutes 90 per cent. were diseased. No typhoid fever occurred and no cerebro-spinal meningitis. Dysentery, fly-carried, did appear, in a few cases amœbic, in 76 cases bacillary (Shiga) with one death. The military hospital of 216 beds was established in a new and hitherto unoccupied school. A bacteriological laboratory was there established, was much used, and controlled all important clinical diagnoses. In consequence of all this "the occupation of Vera Cruz was attended by no higher percentage in the sick rate than for the troops in the United States." The details given in the paper are most interesting, and should be widely read, and Colonel Birmingham and the United States Army Medical Corps must be warmly congratulated on their splendid success.

The Eugenics Review.—The April issue opens with the second Galton lecture by Professor J. A. Thomson, to which we referred at length in our issue of Feb. 27th. This, together with a criticism of M. Guénot's "Preadaptation," by R. A. Fisher and C. S. Stock, and the Causes of Rise and Fall in the Population of the Ancient World, by Professor J. L. Myres, Wykeham Professor of Ancient History at Oxford, form the principal contents of the Review. The latter article gives us a "sample of ancient eugenics," covering 1000 years, and under the guidance of Professor Myres we see "populations overtaking the means of subsistence in a limited region; the relief of this congestion by colonisation oversea; the complete occupation and development of colonial regions; the pacific penetration of the regions of stable or less progressive culture by aggressive civilisation, itself in rapid development; forcible dispossession of obstructive occupants, and no less forcible elimination of competitors for maintenance within the home circle of the conqueror." "History," he says, "is as surely as geology a comparative science, and in the light of ...... fossil politics ...... we can estimate the outcome of policies and modes of life." He recognises, however, that we cannot be sure that no catastrophe will occur to change the course of nature altogether, and with this reservation the article is opportune when we are all speculating as to the probable course of history after the war.

The Cornhill.—To the May number of the *Cornhill* Mr. Gilbert Coleridge contributes a very human and valuable article, entitled "Thinking in Open Order." "We are," he says, "apt just now to blame the Kaiser personally for the atrocities committed by the German army in Belgium and France, but he is only responsible in so far that he has made no effort to discourage acts which were the logical result of the collective military training and habits of thought of his people. The point of view is well expressed in 'Friedens- und Kriegsmoral der Heere,' which Mr. William James quotes in his 'Varieties of Religious Experiences,' where the following frank statement appears: 'If the soldier is to be good for anything as a soldier, he must be exactly the opposite of a reasoning and thinking man. War, and even peace (*sic*), require of the soldier absolute peculiar standards of morality. The recruit brings with him common moral notions, of which he must seek immediately to get rid. For him victory, success, must be everything. The most barbaric tendencies in man come to life again in war, and for war's uses they are incommensurably good.' Whereupon Mr. James justly remarks: 'When we gravely ask ourselves whether this wholesale organisation of irrationality and crime be our only bulwark against effeminacy, we stand aghast at the thought, and think more kindly of ascetic religion.' How far the German soldier has been 'exactly the opposite of a reasoning and thinking man' his exploits in towns and in the open field will testify. The nation in its drunkenness has set out to paint Europe red, and is making a night of it; but 'after the shrimps, the bill'; after the orgy comes the headache in the morning, and when the light of truth breaks in upon a hungry peace and shows to the reveller the havoc of the night, it is possible we may keep a grain of pity for the deluded people who took no heed of what other nations thought, stifled independent criticism, and carefully arranged their thinking in close order. But not till after the handcuffs are on. It may be that they will readopt 'common moral notions.' Possibly they may come to realise that cleverness and thoroughness are not incompatible with sheer stupidity."

THE MEDICAL MAN'S INCOME-TAX.

(Concluded from p. 878.)

Circumstances in which Relief is Allowed.

THE importance of the accurate completion of the form of return under "Schedule D" may be gathered from the fact that there are at least five classes of relief which are allowed only when they are duly claimed—that is to say, the allowances for life assurance premiums, abatement, and children, and the separate reductions of duty admitted on earned incomes and on all incomes below certain limits.

The circumstances in which each description of relief is allowed are as follows:—

Life Assurance.—All annual premiums payable in 1915–16 on the life of the practitioner or his wife up to a limit of one-sixth of the total income, including annual sums paid for deferred annuities and on accident policies that cover the risk of death, and also a proportion of the premiums paid on combined (sickness and accident) policies that cover the risk of death.

Abatement of £160, £150, £120, or £70, where the total joint income of husband and wife does not exceed £400, £500, £600, or £700 respectively; total exemption where not exceeding £160.

Earned Income Relief.—A reduction of duty on the portion of the income that is earned, governed by the amount of the total income from all sources. The relief at present is at the rate of 1*s.* in the £ where the total income is under £1001; 9*d.* where under £1501; 6*d.*, under £2001; and 2*d.*, under £2501; and the reduction is allowed on the income remaining after the deductions for abatement, &c., have been made.

Small Incomes Relief.—This applies, in effect, to the income that would otherwise be charged at the full rate of tax, and is limited to cases where the total income from all sources does not exceed £500, the allowance being at the rate of 2*d.* in the £, unless the total income does not exceed £300, when the allowance is 6*d.* in the £.

Children.—An allowance of £20 from the assessment for each child or stepchild living and under 16 years of age on April 6th, 1915, where the total income does not exceed £500.

The cumulative effect of these rebates will best be explained by means of an example. Suppose a practitioner to earn £450 a year, to own a small property assessed to income-tax Schedule A on £25, to pay £30 in life assurance premiums, and to possess two children under 16 years of age, and a wife who has an income of £20 from dividends. His "total income from all sources" will be £495, of which £450 is earned. He will be entitled to an abatement of £150, allowance of £40 for the two children, and £30 for the life assurance premiums, leaving £230 professional income on which tax is to be charged. This £230 will, if present rates continue, be charged at the rate of 1*s.* 6*d.* (after allowance of the "earned income" relief of 1*s.* proper to an income below £1001), and he will further be entitled to the "small incomes" relief of 2*d.* in the £ on his property and on his wife's dividends. He should therefore be charged on £230 at 1*s.* 6*d.*, less £45 (£25 + £20) at 2*d.*, making £16 17*s.* 6*d.* net in addition to the tax paid on the property and dividends.

The Completion of the Return.

In completing the form the first step is to enter in Section B the amount of the professional profits on the average of the three years 1912, 1913, and 1914, after deducting the professional expenses, as previously explained, but without deduction for life assurance premiums. The words "including receipts from public appointments" should be added if such receipts have been included; otherwise the appointments should not be referred to on this page. In Section B should also be entered any other untaxed income that the practitioner may receive, such as bank interest, but not dividends paid "free of tax," an expression which means that the company has deducted the tax in computing the dividends. If the practitioner desires that his return should not come before the local Commissioners and collector he should here apply to be assessed by the Special Commissioners in London, a course frequently adopted by medical men.

The statement of total income from all sources to be made in Section D is of the greatest importance, since it is on the strength of this statement that the allowances for abatement, earned income, and small income relief are made. The declaration is required to show, in the first place, the professional income that has already been returned in Section B, and in addition the receipts from public appointments, unless these have been included in calculating the general professional income. Under the head of "property" should be entered the annual rentals, less one-sixth for premises that the owner repairs and less one-eighth in the case of land. Where the practitioner both owns and occupies the property the figure to be entered is the net assessment on which income-tax, Schedule A (property tax), has been paid, and it will often be found convenient to adopt this basis for all property. The space provided for income from the occupation of land applies only to persons occupying land other than an acre of garden round a house, the profits from such other land being taken at one-third the rental value. Interest and dividends which have been taxed before receipt (or entered in Section B) should be shown in the space provided, on the basis of the 1914 income, unless there is reason to suppose that the 1915 income will be materially different, in which case an estimate might be made. Full details are not usually required under this head, nor under the following head of Wife's Income, provided the income can properly be described as "taxed before receipt." Although a wife's income is required to be included in the statement, a practitioner who prefers not to set it out separately may include it with his own under the various heads and make a note on the form that he has done so. It may be remarked that where husband and wife conduct independent practices or otherwise earn money independently of one another, and the total joint income is under £500, they are entitled to two separate abatements.

There follows on the form a space for "charges on income," in which should be entered annuities, interest, ground rent, and other sums which the recipient of the income has to pay away to others. In making such annual payments income tax should be deducted from them at the full rate of tax, and the full rate will accordingly be charged on these sums, whatever relief may be allowed on the practitioner's other income.

Section E, which is provided for particulars of the life assurance premiums, presents no difficulty; and Section F, the claim for relief for children, calls merely for a list of the children born after April 6th, 1899, and before April 7th, 1915.

Partnership Income.

Section G of the form is devoted to a return to be made by the leading partner in a firm, or, where there is no precedence, by the partner whose name usually appears first in partnership documents. The partner on whom devolves the completion of this declaration is responsible in the first place for making the combined return of the partnership profits in one sum in Section B, and then for showing in the section now under consideration the manner in which the assessment should be apportioned between the partners. The return in Section B will be the total average profits of the joint practices for the three years 1912, 1913, and 1914 (after deduction of all expenses, including the expense of any separate professional establishments of the partners), and the idea of Section G is to indicate how this figure would be apportioned between the partners at the rate of division that will apply in the year 1915–16. Where the proportionate shares have varied over the three years that fact is immaterial; only the current rates of division have to be considered. The completion of this section is often found troublesome, but becomes comparatively simple if it is borne in mind that the object is to show how much each partner would draw in 1915 if the partnership profits for that year were equal to the sum returned for assessment. Thus, suppose the average profits to be returned at £1000, subject to a charge of £100 a year for interest or annuity to a third party, the sum to be divided will be £900. A is perhaps entitled in the year 1915 to draw £60 by way of special salary or interest and two-thirds the balance, B receiving the remaining one-third. The apportionment will then be shown as: A £620 (£60+£560) and B £280 (one-third of £840). There are, of course, cases in which the proper apportionment of the sum returned for assessment will have to be a matter of agreement between the partners on consideration of the normal professional expenses of each.

It is to be observed that although a combined return is required to be made of the partnership profits, each partner is personally entitled to a deduction from his share of the assessment on account of whatever allowance may be due to him in the way of abatement, life assurance, earned income relief, &c., and these he must claim on a separate form by completing Sections D, E, and F in the manner explained above.

Successions.

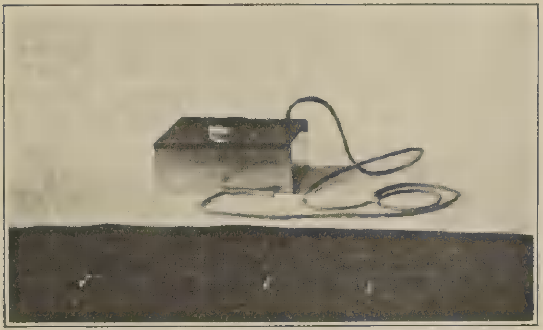
The successor to a practice is required to declare the average profits of the practice for the past three years to the best of his ability with the information at his command; the profits that he himself may have made elsewhere do not come into the computation. If he should take over the practice in the course of the year he will be liable for his portion of the assessment, but in such a case should communicate with the surveyor of taxes in order to ensure that the allowances to which he is personally entitled are made from the assessment. A successor who finds the profits less than the sum on which he has been charged may always claim relief, but if his profits should be greater that fact does not invalidate the assessment.

New Inventions.

A NEW TELEPHONE PROBE.

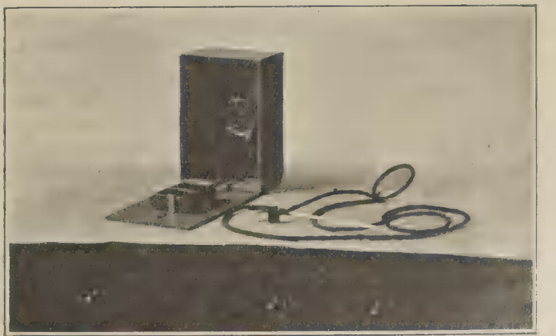
FOR a telephone probe provisionally protected by me last December certain advantages are claimed over others already in use. It should prove useful to the general practitioner for locating needles, &c., as well as to the military surgeon for detecting the presence of bullets or pieces of shrapnel and the like in wounds. The probe consists of a silver rod insulated from a sheath of the same metal, forming the two electrodes. They are attached to a plug by insulated wires encased in rubber tubing. In the lid of the box are fixed the plug-holder, a specially wound telephone, and a dry cell of the ordinary flash-light pattern. The latter, when exhausted, can be replaced for a few pence almost anywhere.

FIG. 1.



Plug of the telephone probe in its holder and the probe ready for use.

FIG. 2.



Interior of the box with the telephone probe detached.

When the plug is in its holder an electric current is established on inserting the probe into a wound, contact between rod and sheath being effected through the moist surfaces. Any disturbance of the flow or interference with the lines of force of the current, such as occurs when a piece of metal is touched by the probe, will be instantly indicated by an audible noise in the telephone. The chief points claimed for this probe are its simplicity, efficiency, and small liability to get out of order, and it can be used by one having no knowledge of electricity, as efficiently as by one well acquainted with its uses. There is nothing to fix on the head of the operator, nor on the body of the patient. The noise in the telephone has not to be listened for, it is quite audible to everyone in the neighbourhood. The probe can be bent about as freely as the ordinary surgical probe, and with its connecting wires and plug forms a unit that can be sterilised by boiling as often as required. It would be an easy matter to make the electrodes the blades of a pair of forceps, or to add a bell indicator, &c.; but while these might add to its interest the possible gain in efficiency would, generally speaking, be more than counterbalanced by the loss in simplicity.

These probes will be obtainable from Messrs. Allen and Hanburys, Limited, and other surgical instrument makers.

David Findlay, M.D. Edin.,
Medical Officer in Charge Electrical Department, West End Hospital for Nervous Diseases.

Reports and Analytical Records

FROM

THE LANCET LABORATORY.

(1) OXYNTIN; AND (2) ENZYMOL.

(Messrs. Fairchild Bros. and Foster, Albert Chambers, 64, Holborn Viaduct, London, E.C.)

1. Oxyntin is a light cream-coloured powder containing albumin combined with hydrochloric acid. It is miscible with water, the solution having a slightly acid taste. We found that the amount of acid present was just under 5 per cent. Oxyntin usefully replaces dilute hydrochloric acid in the treatment of gastric disorders. It is convenient for administration, and provides in that way a standard amount of hydrochloric acid. 2. Enzymol is a clear solution which shows great proteolytic activity analogous to that of the gastric juice. According to our examination, it acts rapidly on blood fibrin. It is specially prepared for external application as a solvent of albuminous matter, as, for example, false membrane in diseased and sloughing tissues. Its active proteolytic properties allow septic matter to be easily removed by irrigation.

DIFFUSOL.

(W. Martindale, 10, New Cavendish-street, London, W.)

Diffusol is an alkaline, soapy solution of specially purified ortho-, meta- and para-cresol. For surgical purposes the selection of a practically water-white and nearly odourless cresol is important. The diffusible and penetrating properties of this preparation were referred to in the recent Hunterian oration. We confirmed the statement that diffusol contains 50 per cent. of cresol by decomposing it with calcium chloride and caustic soda. On filtration the cresols are obtained in alkaline solution from which they are readily separated by the addition of an acid.

MALT EXTRACT WITH PARAFFIN.

(A. Wander, Limited, 43, Cowcross-street, London, E.C.)

In spite of this preparation presenting the appearance of a crystalline compound it contains, according to our analysis, no less than 50 per cent. by weight of petroleum, which confirms the statement made by the makers. With water it forms a perfectly uniform emulsion resembling milk. The fluid so obtained readily liquefies starch jelly, ultimately converting it into dextrin and sugar. The taste is pleasant, and the preparation affords an agreeable and effective way of administering petroleum for its laxative properties. The digestive action of the diastase present has therapeutic advantages also.

ANTIFORMIN.

(Messrs. Sutton and Phillips, The Factory, Stowmarket.)

Antiformin possesses both powerful detergent and antiseptic properties. It is a carefully balanced combination of hypochlorite of soda with sodium hydrate. We found present 4·12 per cent. of available chlorine and 7·6 per cent. of alkali. Its dissolving action on various organic matters, dirt and grease is of great assistance in the work of disinfection, while chlorine, of course, is a powerful germicide. Besides of use in the refinements of antiseptic practice as for sterilising surgical instruments and application in diluted form in skin diseases, it is useful for household cleansing. Recent studies have shown how very powerful the hypochlorites are as germicides in the sterilisation of water, so that very dilute solutions are effective. These considerations suggest application in surgical and medical practice more than has hitherto been the case. Antiformin has already been used with advantage in the bacteriological diagnosis of tuberculosis.

CREAMWORT.

(The Glenn Company, Garwick, Isle of Man.)

This is a preparation of milk soured by a special lactic acid ferment. Lactic acid bacillus therapy has been on its trial for some time, and no doubt in many cases gives good results, but it is important that the sour milk should contain no adventitious matters or organisms. Creamwort reminds us of the curdled milk preparation called yaghourt which is consumed so largely in Turkey and in Bulgaria. It has a strong but pleasant acid flavour. Our analysis gave the following results: Moisture, 89·53 per cent.; mineral matter, 0·76 per cent.; fat, 3·00 per cent.; milk sugar, 2·30 per cent.; lactic acid, 1·97 per cent.; and casein, 2·44 per cent. It thus shows the composition of sour milk. It possesses both nutritive and therapeutic properties, the lactic acid development being useful in intestinal auto-intoxication.

MINERAL WATERS.

(Richard Davis, 20, Maddox-street, Regent-street, W.)

It is reported by this well-known manufacturer of mineral waters that the demand for these beverages has grown considerably since the war, which has led him to pay still further attention to their preparation. He has submitted to us samples of dry ginger ale, lemonade, tonic water, and ginger-beer. We have examined these and find they are well made, and in no case was any trace of objectionable preservatives or metallic contamination found. They are quite wholesome beverages and we are glad to note that the amount of sugar present is not excessive. The ginger ale may well be described as dry, and it has a quite delicate flavour. It was free from sulphurous acid. The stone ginger-beer is also a well-made beverage. Being fermented it contained a small amount of alcohol equal to 0·66 per cent. by volume, which is well below the limit laid down by the excise.

THE LANCET.

LONDON: SATURDAY, MAY 1, 1915.

Nerves and War: The Mental Treatment Bill.

In the campaigns of the last century, and notably in the Franco-Prussian War of 1870, the strain of battle and the arduous conditions of active service were recognised as prolific sources of nervous and mental disorder. The development of military art since then, characterised as it has been by great and rapid progress in the discovery of increasingly powerful explosives and in their utilisation for destructive ends, has added very materially to the nerve-shattering influences of war, while with the larger scale of operations and the employment of huge conscript armies the range of these influences has been enormously multiplied. As a result the problem of dealing with cases of nervous and mental disorder in soldiers on active service has become at the present day a matter of serious difficulty and of considerable practical importance.

The procedure which has been followed hitherto in regard to cases of this sort occurring in the Expeditionary Force is very similar to that adopted in ordinary surgical and medical practice in the field. Specialists of acknowledged standing in the profession are attached to the large hospitals overseas, and are called in to examine and report on all cases of traumatic neurasthenia and the milder psychoses. Under their instructions the patients are sent home to one of two clearing hospitals—viz., the Royal Victoria Hospital, Netley, and the 4th London Territorial Hospital at Denmark Hill, where special neurological sections have been organised, and they are thence transferred according to the exigencies of the individual case, either to one of the London hospitals for nervous diseases or to one of the institutions taken over by the military authorities for use as hospitals. The fact that several of these latter institutions were formerly lunatic asylums has given rise in some quarters to a feeling of anxiety lest the soldier patients sent there for treatment are being relegated to the category of the insane and may suffer in after life from the prejudice which the vulgar unfortunately entertain against the victim of mental disease. This feeling has found expression in a memorial to Lord Kitchener suggesting that arrangements should be made for treating soldiers suffering from nervous shock in specially organised departments in connexion with general hospitals. It is possible, if we may judge from the terms of the memorial, that some supporters of this view have been influenced by a needless suspicion of the lunacy expert, and have quite erroneously supposed that the alienist goes about seeking whom he may certify; but that qualifying consideration should not prevent us from recognising that the feeling voiced in the memorial is in itself a natural and proper feeling, and one, moreover, which we venture to think is shared by the large majority of alienist physicians. For years past alienists have been striving to impress on the public mind the urgent need of bringing the treatment of insanity into closer association with general medicine by the establishment of psychiatric clinics in connexion with the universities and the larger hospitals, and they have confidently maintained that by making proper provision in this way for the early treatment of incipient and undeveloped mental disorder it would be possible to save many patients who under the present system drift into incurable insanity.

A statement of this view was formulated shortly after the outbreak of the war by one of the members of the Board of Control, Dr. C. H. Bond, in his introductory address at the opening of the winter session at the Middlesex Hospital[1]; and it is hardly necessary to recall that the Maudsley Hospital, which will perpetuate the name and the generosity of one of the foremost living alienists, was designed by its founder to embody the same ideal. The advocates, therefore, of what may be termed the abortive treatment of the nervous disorders occurring in our soldiers under the strain of war can count on the sympathy and coöperation of the specialists in psychiatry; and this the more certainly because the cases which we are considering are peculiarly amenable to this mode of treatment. It is, in fact, well known that a very large proportion of the psychoses of soldiers on active service are of an eminently recoverable character. Dr. P. M. Awtokratow, who, as the medical officer at the head of the organisation for the care of the insane in the Russian army during the Manchurian campaign, had exceptional opportunities for studying this question, found[2] that most of the cases of epileptic psychosis and neurasthenic insanity—the commonest forms of mental disorder occurring amongst the Russian soldiers—recovered completely under appropriate treatment within three or four weeks. Presumably the same good results may be looked for in the majority of the confusional and neurasthenic cases sent back from the battlefields of Flanders, so that it would be obviously undesirable to apply to such cases the methods of certification and legal restraint that have to be used in dealing with graver and less curable forms of insanity. And as these invalid soldiers are subject to military discipline, the difficulties which unfortunately compel the resort to certification in similar cases occurring in civil life do not arise; in the army patients suffering from these incipient and unconfirmed disorders can be kept in hospital as long as competent medical opinion considers necessary without putting upon them the stigma of legal insanity. And here we may remark in passing that a modification of the law, giving to the physician in charge a similar power of limited control, is a necessary preliminary to the establishment of psychiatric clinics for the treatment of incipient mental and nervous troubles in civilian patients. The critics of our present lunacy system would do great service if they would devote some part of their energies to promoting this reform.

---

[1] The Lancet, Oct. 17th, 1914, p. 935.

[2] Die Geisteskranken im Russischen Heere während des Japanischen Krieges, Allgemeine Zeitschrift für Psychiatrie, 1907.

In the meantime a Bill, the Mental Treatment Bill, has been introduced into the House of Commons by Mr. CECIL HARMSWORTH, the Under Secretary for Home Affairs, the purport, briefly stated, being "to facilitate the early treatment of mental disorder of recent origin arising from wounds, shock, and other causes." Its text has now been issued, and a Memorandum attached to it gives a brief summary of the law and the changes which it is proposed to effect in it. The object of the Bill is to secure the proper treatment of such cases by making the law less rigid than at present. It removes the necessity for formal certification in the case of persons suffering from mental breakdown of recent origin and arising from wounds, shock, &c. In this respect it assimilates the English law to the law which has been in force in Scotland for 50 years and which has worked satisfactorily [Lunacy (Scotland) Act, 1866, section 13]. This Bill will enable a man who, in the service of his country, has suffered a nervous breakdown, to accept the treatment without being certified, but only for a period not exceeding six months and under conditions which should provide security against misuse. The measure will be criticised as annulling the protection of the Lunacy Act by providing for detention in cases that are not properly certifiable, and as introducing unnecessary legislation, because there is nothing in the Lunacy Act which precludes medical care being bestowed upon such cases in homes or institutions where, moreover, invalid soldiers can be required to remain by military authority; but the medical advisers of the War Office are, of course, alive, we must believe, to the special conditions of the problem, and we feel that they should be trusted to ensure that soldiers suffering from nervous shock will be treated by the best possible methods and with the help of all the resources of medical science. We do not think that there is ground for fearing that resort will be had without real and urgent necessity to any procedure likely to be prejudicial to the patient's prospects in after life. It is right, however, that public attention should be drawn to this side of the situation; the interest awakened thereby should do much to promote a more sympathetic attitude towards the general problem of the treatment of the insane, and should materially assist the efforts of those alienist physicians who are striving to break down the artificial and mischievous barriers which, in popular belief, and to a regrettable extent even in medical practice, separate insanity from other conditions of disease.

The Treatment of the Sick and Wounded in the War.

SIR ALMROTH WRIGHT'S address to the Royal Society of Medicine closes with an outspoken statement on the organisation of medical service at the war, in which he makes the distinct point that in the existing circumstances medical opinion at large should carry great weight. He points out that military medical activities fall under three heads—treatment in the field, sanitation in the field, and treatment in military hospitals, where the differentiation between base hospitals and clearing hospitals cannot in this enormous struggle be maintained with any rigidity. The energies and organisation of the Royal Army Medical Corps are all employed, and at full stretch, in coping with the exigencies arising under the first two heads of the classification—and how well, with what courage, resourcefulness, and adaptability they have met those exigencies the world bears witness—leaving the treatment of the sick and wounded in the large hospitals mainly in the hands of civilian physicians and surgeons who have met the call upon them with enthusiasm. This state of affairs must continue, and the question which Sir ALMROTH WRIGHT puts is whether the medical service of the hospitals as a whole would not gain by official pronouncements in respect of procedure—whether the patients would not benefit by treatment according to some accepted principles, accepted, of course, after anxious investigation by recognised authorities; and whether the physicians and surgeons concerned would not welcome general guidance, seeing that their individual experiences must vary so much.

The classification of medical work at the war into the three headings of sanitation, treatment in the field, and treatment in hospitals, is perfectly sound, and it is a fact that the third section of labour, the treatment of the sick and wounded in the military hospitals, has largely devolved upon civilian practitioners, who are justly proud of their responsibilities. That being so, it is the duty of us all to consider whether the methods under which this work is being done are those that are calculated to extract from the members of the medical profession engaged the fullest value to their country in her need. And an expression of opinion on that subject from the medical profession at large will not be considered by the Army Medical Service as intrusive; for that service has been, from the moment that the scope of the task before the country could be envisaged, ready in every way to rely upon the best coöperation of national medicine. It is not a question of civilians criticising army orders; rather it is a question of the medical profession deliberating whether their share in maintaining an army with which to fight the Germans would not be more fruitful if those of them now serving as commissioned officers were put in receipt of more orders. Of course, all the treatment of the wounded in the military hospitals has the appearance of military organisation, but, as a matter of fact, the routine pursued must be very much that which, tested by experience and hallowed by custom, is pursued in big civilian hospitals. Now in civilian hospitals, and still more in general practice, which follows the lessons learned in the hospitals, work tends to conform to a pattern. Its variety is great, but the points between which variation occurs are at small distance from each other. There are answers which it is recognised should be given to most large questions of diagnosis or treatment which arise; and every step can be taken with authority, either because the men who move are in a position to know, or because the course to be pursued has been pursued previously by such tried men. How has this position been arrived at? We all know that it is the outcome of years of intelligent routine in a sphere whose limits are bounded by the circumstances and possibilities of civil life, a sphere which has been enlarged as our recognition of the facts of pathology has widened, and which has contracted as medical science has been able to combat and remove certain diseases from among us, or to alter the frequency of their occurrence. In the civil hospitals by careful study of the conditions within their sphere a line of treatment has been arrived at. Not a hard-and-fast line, but a line of common consent, admitting of much fluctuation and ready to alter its situation upon good cause being shown. But the mark of authority is there, and can be constantly maintained by the watching of cases remaining long under the eyes of intelligent observers, and by the collation of opinions derived from others, where the medical press has played, and plays, a great part. In our military hospitals the whole situation is entirely different. The injuries which are found most commonly in their wards are for the most part extremely rare in civil practice. The circumstances in which these injuries have been received are no less novel, for the size of the armies engaged in itself introduces problems, while the advances made in the manufacture of weapons of destruction have endowed projectile wounds with features which have never come within the experience of those employed in treating them. The medical men who are serving in the military hospitals can meet the calls of civilian practice of all sorts, but they are, in their present posts, without the assistance of strong precedents, and without much opportunity of benefiting by the opinions of their colleagues. In the new conditions there are no recorded experiences of value, and few of the cases remain for a sufficiently long time under treatment in one hospital for the medical officer to know if his measures have taken good effect. The service in the military hospitals is weakened by a want of central direction which is all the more needed that peripheral efforts are individual, and have never obtained the force of collective actions.

Our sick and wounded are receiving extraordinarily good attention in the military hospitals, and it is far from our intention to be alarming. One injury does to a great extent imitate another, and some of the best informed exponents of our art are with the Expeditionary Forces. Again, adaptability to the new work has already distinguished a great many of the civilian doctors engaged, while the absence of disease has been notable and the percentage of recovery from serious injury quite gratifying. But none the less we think that Sir ALMROTH WRIGHT has made out a case for the introduction of central guidance in questions of treatment, premising, of course, that any authority set up should be entirely subordinated to the Director-General of the Army Medical Service. The principle has to some extent been recognised by that service, for we published last week a Memorandum on the treatment of bacterial infections of projectile wounds by Sir ALMROTH WRIGHT and three other distinguished civilians, serving in a consultative medical capacity with the Expeditionary Forces, in which these leading surgeons and pathologists give a synopsis of their experience in connexion with the wounds in this war.[1] This synopsis they have supplemented by setting out the chief data furnished by a bacteriological study of the wounds, and they have laid down certain broad maxims of treatment for the instruction of those who have not seen the conditions in the present war, or who have seen only an early or a late phase in the history of the wounds. Moreover, it is promised that this Memorandum will be followed up, as soon as certain researches are completed, by similar information on the employment of antiseptics and vaccines respectively. It is certain that all who have the charge of the sick and wounded in the war must welcome such publications warmly; the question only remaining, whether a step further should not be taken and a regular authority constituted to promote the utilisation of such first-hand knowledge, and to facilitate the adoption, as general measures of treatment, of the lessons so conveyed. We see no inconvenience in the proposal from the point of view that scientific freedom would be interfered with. The dictator in medicine is impossible, but organisation is not tyranny, and leadership based on first-hand experience is not tyranny either. It must be taken for granted that no new machinery introduced would alter in the least the paramount position of the Director-General of the Army Medical Service; and it could only work with the approval of the consulting medical officers, who have been chosen as fully representative of British medical science. But we feel that Sir ALMROTH WRIGHT has made out a good case for the institution of an Advisory Committee charged with the duty of synopsising the clinical experience of the war, being themselves at the seat of war and prepared to take full responsibility for their recommendations. Such a body would instruct and reinforce those responsible for the treatment of the sick and wounded in something the way that past teaching, opportunity for consultation, and familiarity with the conditions support the practitioner in civilian practice. Moreover, such a committee would lead directly to international coöperation. It would enable the good work done by the British medical profession to be more readily available for our Allies, and would give a basis upon which the British procedure could be compared with and modified in accordance with the scientific procedure of our Allies.

---

Annotations.

"Ne quid nimis."

MEDICAL CERTIFICATES AND THE EXPLOITATION OF THE MEDICAL PROFESSION.

Sir John Moore read a paper recently before the Section of State Medicine of the Royal Academy of Medicine in Ireland, in which he drew attention to what he regarded as a serious professional grievance. He referred to the fact that the demand made upon the time, patience, and responsibility of registered medical practitioners in respect of medical certification for State or personal purposes was always made with the offer of a nominal fee, or, as in the case of the medical certificate of the cause of death, with no fee at all. Sir John Moore gave as an extreme instance of the situation the ordinary certificate of death which all medical men are compelled to furnish under penalty. This certificate, he pointed out, is solely for the use of the registrar, given in order that the Registrar-General may be able to compile reliable statistics. For giving this certificate, which is primarily for the use of the Government, medical men are paid no fee, and, we may add, in agreement with Sir John Moore's view, that the circumstances in which such certificates can be given are highly unsatisfactory. Sir John Moore then referred to the arrangements for medical certificates under the Infectious Diseases Notification Act, the Public Health Amendment Act, the Tuberculosis Prevention (Ireland) Act, and the National Health Insurance Act, and criticised with particularity the various circumstances. Under the Public Health Amendment Act the medical officer of health is required to give certificates free of charge to school children who have recently recovered from infectious fevers; under the Tuberculosis Prevention (Ireland) Act a medical man must notify cases under penalty, and for doing this he will get a fee of 2*s.* 6*d.* if the case has not already been notified by someone else; and under the National Health Insurance Scheme certification is allowed to be quite unsatisfactory, as may be gathered from the Report of the Departmental Committee on Sickness Benefit Claims under the National Insurance, July 24th, 1914. The committee then expressed the opinion "that in view of the difficulties with regard to certification, it is necessary that there should be established as soon as possible a system of medical referees." The Chancellor of the Exchequer did not provide for remuneration out of State funds for the medical profession who would be called upon to certify under the Bill: he made provision for the Approved Societies and for the insured, but the medical profession did not enter into his calculations. Sir John Moore claimed that the State can be seen to place but a small, an insignificant, financial value on medical certificates—that, in fact, it "exploits" the medical profession on the matter of certification. We have often in THE LANCET called attention to the demands made by the general public on the medical profession for certificates of good or bad health for insufficient fees or with no fee at all, and we find ourselves wholly on Sir John Moore's side. The public does not understand the justice of the medical claim for adequate remuneration for certificates; a false estimate has been established in the mind of the public as to the value of the medical certificate, and we fear that it will be a long time before the position of scientific medicine in this connexion will be appreciated.

MINISTRIES OF PUBLIC HEALTH.

CONGRESS after congress dealing with public health questions has met in England and on the continent. During the course of such proceedings convincing arguments have been adduced and emphatic resolutions passed advocating the institution of a Ministry of Public Health. Nevertheless, nothing of the sort has been done in any of the countries concerned. Will the war now bring about what all these assemblies, some of them of great importance, have failed to accomplish? There are rumours to that effect. With regard to France, 20 years ago Dr. Pierre Bonnier studied and discussed a scheme for a Ministry of Public Health with his party colleagues, M. Millerand and M. Jules Guesde. (It is significant that to-day the former is Minister of War and the latter a Member of the French Government.) M. Vaillant, the *député* who, when an exile here qualified as a Member of the Royal College of Surgeons of England, drew up a scheme more recently which was submitted to the Chamber of Deputies for the creation of a Ministry of Public Health. Nothing was done then, but the signs are now propitious, and if the reform comes it may come all in a moment. At congresses innumerable, and on many public occasions, more was said for years against absinthe than has ever been said in favour of a Ministry of Public Health. To-day the sale of absinthe has been abolished with a stroke of the pen. Russia, which abolished vodka with similar ease and expedition, is also stated to be contemplating the possibility of calling into existence a Ministry of Public Health, and from Roumania we hear of the same intention being manifested. The swift compliance with the demand for a Public Health Ministry in France would have its origin in the circumstances of the war. The mobilisation of the ambulance services in France was not at first as satisfactory as might be desired. Centralisation with expert knowledge would have done better. And if to-day we hear that proposals have once more been brought forward in France to instal a new Minister of Public Health it is in order to have someone who will be in authority over civil State medicine and give official help to military medicine, Red Cross work, and national and international public health services. Thus it may happen that the stress due to the war will bring into existence in France, and with but little difficulty or resistance, what has been talked about in vain for so many years. If a Ministry of Public Health is instituted in France, it may not be long before this country follows suit.

PELVIC ABSCESS AFTER THE USE OF THE FOWLER POSITION.

THE Fowler position has proved a valuable advance in the treatment of cases of suppurative peritonitis. In the *New York Medical Journal* of Feb. 13th Dr. H. B. Delatour has called attention to a complication which may follow its adoption after operations for appendicitis. While in the majority of cases the septic material which gravitates into the pelvis drains away, in a few cases pelvic abscess results. His attention was first called to this complication by the following case. A young man underwent operation for acute appendicitis. The abdomen contained a large quantity of purulent serum. The appendix was perforated and gangrenous about the middle. After its removal as much of the fluid as was in the wound was sponged away and a cigarette drain was introduced into the pelvis. The wound was partially closed and the patient placed in the Fowler position. He was recovering satisfactorily when, at the end of a week, he began to complain of pain in the left iliac region and the temperature rose. Two days later an incision was made on the left side, and an abscess in the left iliac fossa was opened and drained. The temperature fell, but not to normal. He then suffered from diarrhœa and pain on defæcation, which he attributed to "piles." When seen by Dr. Delatour he had an almost continuous desire to defæcate, but passed only scanty motions containing much mucus. Examination showed no hæmorrhoids or evidence of ischio-rectal abscess. Introduction of the finger was painful, and just beyond the prostate a mass was discovered bulging into the rectum. This felt so like a distended bladder that this organ was emptied before proceeding further. The mass was still present and gave a sense of fluctuation. Under ether the sphincter was dilated and a speculum introduced. The bulging anterior wall of the rectum was cleansed with sponges, and a longitudinal incision led to the escape of 3 oz. of pus. A drainage-tube was introduced and brought out through the anus. On the fourth day it was removed, as all drainage had ceased. After the evacuation of the pus the temperature became normal and the general condition began to improve. Two weeks later recovery was complete. This complication does not appear to be very rare, for since the occurrence of this case three years ago Dr. Delatour has observed six similar cases. They were all treated in the same way except one. In this, as the abscess was small and far from the anus, aspiration was tried. Two ounces of pus were withdrawn and recovery followed. Dr. Delatour concludes that if after operation for appendicitis the wound looks healthy and careful examination shows no undrained pockets and yet there is pyrexia a rectal examination should be made, especially if there is frequent defæcation with tenesmus and discharge of mucus. If an abscess is present he recommends drainage by the rectum. There appears to be little danger of infection from this source. To wait for the abscess to be reached easily from the front would be to lose valuable time, and the incision through the abdominal wall would leave a weak point for the development of a hernia, as drainage must be continued for some time. While aspiration may prove satisfactory in some cases Dr. Delatour recommends incision whenever possible. Incidentally, he remarks that a large percentage of cases reported as general suppurative peritonitis are not so. In many cases of acute appendicitis he has found the abdomen full of serum clouded with lymph. For some reason an unusual amount of serum has been exuded without changes in the peritoneum which could be recognised as inflammatory. In such cases it has been his custom for years if the appendix, though gangrenous, is not perforated to close the abdomen without irrigation or drainage, and the results have justified the procedure. The success of many cases of this kind appears to have been credited to postural treatment.

MEASURES FOR DISINFECTION.

THE Local Government Board for Scotland has recently issued a circular to public health authorities requesting information as to the measures adopted in the district of the local authority for the disinfection of clothing and dwellings. With the circular a form of inquiry is enclosed to be filled up by the medical officer of health or the sanitary inspector. Section A in this form relates to wearing apparel, bedclothes, and bedding infected by persons suffering from the ordinary infectious diseases, as typhoid fever, diphtheria, scarlet fever, measles, whooping-cough, and chicken-pox. The questions in this section refer to whether it is the practice to remove to one or more central stations any or all of such articles, and if so whether the disinfection method is by steam, gaseous or liquid disinfectants. In the case of the disinfection being carried out at home information is asked as to the disinfectant employed and the duration of the exposure of the infected articles to the disinfectant, together with the measures adopted for the disinfection of the dwelling apart from clothing. Section B refers to wearing apparel, bedclothes, and so forth infected by patients suffering from tuberculosis. The questions asked as to procedure are much the same as in Section A, but any difference in regard to treatment of pulmonary and non-pulmonary tuberculosis is requested to be notified. The issue of this circular would appear to mean that there is a desire to place methods of disinfection on one effective level. A system of uniformity in this matter is certainly needed, and it is to be hoped that the information asked for will be supplied in order that standard and effective methods may be universalised.

THE DEFICIT IN THE INSURANCE DRUG FUNDS

OWING to a shortage in the amount allotted for the payment for dispensing and medicines for insured persons panel chemists in many districts have suffered both in 1913 and 1914, but especially in the latter year, the uncomfortable experience of being confronted with the prospect of having their bills discounted more or less heavily. But the situation has now been considerably relieved by a statement made by Mr. E. S. Montagu, chairman of the National Insurance Joint Committee, to a deputation from the Pharmaceutical Society which waited upon him with regard to this and related topics. He said he had come to the conclusion that a case had been made out for some relief to be given to chemists whose bills had suffered a heavy discount, and he therefore proposed to make available, for the purpose of *ex gratia* payments on this account, the special drug fund, for which a sum of £60,000 had been granted by Parliament in 1913 and 1914. These payments, he said, must not be regarded as a precedent, and were intended solely to meet the abnormal conditions which had arisen in the first two years of the operation of medical benefit. This sum will be far short of sufficient to enable the whole of the deficits to be made up, but those panel chemists whose bills have been heavily discounted are nevertheless to be congratulated on the fact that through the instrumentality of the council of the Pharmaceutical Society they will receive a substantial proportion of money which there seemed reason to believe was irrecoverable. It is to be hoped that this unbusiness-like system of discounting bills will be discontinued, and that some means will be devised of putting the pharmaceutical finances of the Insurance Act on some equitable basis which conforms with established notions of business transactions. Mr. Montagu also outlined an arrangement by the operation of which panel chemists will not be kept waiting so long for the payment of their bills.

"LEARNING FROM OUR ALLIES."

IN another column Dr. Dundas Grant draws attention to the collection of special classes of cases in certain military hospitals of France. These hospitals constitute centres to which cases from far separated regions are brought together, and we agree with his suggestion that those called upon to deal with these special forms of injury may derive a considerable amount of information by visiting such centres. Evidently the plastic surgery of the face is richly illustrated in such "services" as those of Dr. Morestin at the Hospital of the Val-de-Grâce in Paris and of Dr. Moure and Dr. Dubreuilh at Talence, near Bordeaux. The stomatological department at Bordeaux appeared to Dr. Dundas Grant to afford great advantages for the study of the methods of repairing damage to the masticatory apparatus and impressed him with the immense importance of the dental surgeon's chair in the treatment of injuries to the jaws occurring in warfare. We hope that a regular system of interchange of experiences between the military medical services of the Allies will soon be instituted; there is every indication that both the present needs of the wounded and the progress of medicine in the future would be helped by such a pooling of the results of actual work.

DIAPHRAGMATIC HERNIA OF THE STOMACH AND OMENTUM ON THE RIGHT SIDE.

A CASE which is probably unique has been reported by Dr. Kakels and Dr. Basch in the *New York Medical Journal* of March 13th. It was found at the operation which was performed for the relief of the symptoms that the whole of the stomach except its pyloric end, together with the whole of the great omentum, was in the thoracic cavity on the right side, outside of and behind the pericardium. The hernial protrusion, which was a true hernia, the wall of the sac consisting of peritoneum and pleura, had passed upwards through an opening high up in the diaphragm on the left side and behind the liver near the left crus between the pars vertebralis and pars costalis. The entire hand could be introduced into the opening and the sac itself extended as high up as the second rib. The stomach itself was enormously enlarged, being three times its natural size and near its pyloric end there was a distinct constriction. The patient succumbed soon after the operation, at which it was found quite impossible to close the hernial opening. The patient was a man, aged 54, and nothing in the history suggested the presence of a diaphragmatic hernia. He had not been subject to unusual strain, and up to two years ago had had good health. Then he had an attack of sudden and gradually increasing pain across the upper abdomen with a feeling of abdominal distension and a condition of mild shock. The further course of the case resembled that of chronic gastric or duodenal ulcer, whilst in the later stages the loss of appetite, weight, and strength suggested malignant disease. There occurred also periodic vomiting of large amounts of gastric secretion. Test meals in this case showed the possibility of an erroneous conclusion being arrived at as to the gastric motility, for in this case only 30 c.c. total contents were removed, suggesting abnormally rapid motility and emptying, but really due to the withdrawal of contents from only one sac of the hour-glass stomach. The X rays were of assistance, and the hour-glass condition was recognised, and the radiologist also suggested the possibility of a diaphragmatic hernia. Some of the plates are reproduced in this paper, and in them may be seen the pushing down of the liver a few minutes after the bismuth meal, and the "oblique white line" of the stomach can be seen on the right side extending upwards and inwards from the eighth rib to the pericardium.

THE CRITICISMS OF CORONERS.

THERE is a tendency constantly to be observed among those occupying judicial positions to criticise members of the medical profession severely who exercise their undoubted discretion as to the acceptance or refusal of patients for treatment in accordance with the circumstances in which such treatment is asked for. This is particularly observable in the case of coroners, who not infrequently hear a story of how a medical practitioner was asked to come at once to the deceased person on whom an inquest is being held, but who declined to do so. If the medical man received the call, and was not physically prevented from answering it, there is a tendency to consider him *ipso facto* convicted of brutality. A refusal to attend a patient who afterwards dies causes grief and resentment among the bereaved relatives, and it is the duty of a coroner to satisfy himself that there is no evidence of neglect to lay before the jury in fixing responsibility for the death in question. Beyond this, however, his duty cannot lie, except that he should be careful to protect a professional man against groundless attacks by excited and naturally prejudiced witnesses. There is no excuse for a coroner who, in the circumstances indicated, lends an ear to complaints which he should know are unjustifiable; he should not give them even a qualified support. But such would appear to have been the line taken by Dr. S. I. Oddie at Wandsworth recently when holding an inquest on the body of a child named Alfred Day, who died from pneumonia, and whom Dr. J. Tod Thyne admittedly was asked more than once to attend during the last 24 hours of life without complying with the request to do so. On the face of this story there may have been a case of hardship suffered by the mother of the child, in spite of the fact that when the medical man was sent for Alfred Day was ill beyond hope of recovery; but, at the same time, the mother was at liberty to summon another medical man. Going below the surface, however, in order to inquire why Dr. Tod Thyne did not attend, the coroner was informed by him that he had treated the child before; that he knew that it was in very bad health, but did not know that there was immediate danger; and that when he was first summoned he had not had his clothes off for 42 hours. To quote his own expression in explaining to the coroner, he was "done up." At this time, moreover, a Sunday evening, his surgery was full of patients waiting to see him and he promised to visit the case early next day. In the night he was, however, called to a confinement which kept him up till 7 A.M., and on Monday morning, when he was once more sent for, his surgery was again full. The coroner made various suggestions: he thought that the medical man might engage an assistant; he said that he might have left his patients waiting in his surgery in order to relieve the mother's anxiety, adding that the patients in the surgery "could not have been more ill than a dying child," a statement which presumed knowledge on Dr. Tod Thyne's part that the child was, in fact, dying. Dr. Oddie concluded by saying "the mother felt very cross when she could not get the doctor who knew the child, and I am inclined to agree with her." This appears to us to be unjust and uncalled-for criticism, and, moreover, to be concerned with a subject outside the scope of the coroner's inquiry. All the circumstances of a medical man's professional practice, his own interest no less than the calls of humanity, demand that he should do his utmost to attend all the patients in need of his aid whenever it is possible to do so, and that he should neglect none. The conditions under which illness occurs do not, however, allow of anything but a general organisation of the work to be got through, such as, for example, a practice of being at certain times of the day in his surgery and at certain other times out upon his rounds. It is not possible for any man to be in two places at once, but the alternative was suggested by Dr. Oddie that Dr. Tod Thyne should engage an assistant. Whether a medical man will take an assistant or not is entirely his own affair, and at the present time assistants are difficult, or impossible, to obtain. Besides, even with an assistant, a rush of work or the clashing of two serious cases which demand simultaneous attention may lead to complaints on the part of someone. We think Dr. Oddie does not recognise the difficulties of general practice, and possibly he is not aware of the practical impossibility of obtaining an assistant.

DENTAL CARIES.

Two papers on dental caries of more than passing interest have recently appeared, the one by Dr. H. P. Pickerill[1] and the other by Dr. H. Ewan Waller.[2] Dr. Pickerill's paper is written in the form of a report to the Sixth International Dental Congress and, although the greater part summarises well-known facts in connexion with the disease, there are sections recounting valuable researches he has undertaken. He is particularly insistent on the disastrous effects of alkalies, and states that they have a depressant action on salivary secretion. The continuous dosage of alkalies he maintains produces alimentary stasis and therefore toxæmia, the latter in its turn producing secondary (nervous) salivary stasis by the direct action of endotoxins, and in this way oral stasis is set up and predisposition to caries brought about. With regard to the question of foodstuffs he gives many facts to show that food prepared in a soft state plays but little part in the incidence of caries, but he thinks that an active factor is the fine subdivision of the foodstuffs. The resistance of the tooth tissue he regards as an important thing, and shows that there is a marked difference in the enamel of the teeth of Maoris, who are comparatively immune to caries, and of Europeans, who are liable to the disease. On the question of heredity as an etiological factor in dental caries he refers to the well-known experiments of Brown-Séquard on the division of nerve tracts in guinea-pigs. The guinea-pigs, Brown-Séquard claimed, produced offspring with lesions similar to those produced in the parents by section of the nerves. Dr. Pickerill remarks: "If these views are correct, the bearing on the occurrence of dental caries is this: that at increasingly early ages, long before marriage, adolescents are, either by disease or by operations, suffering section or destruction of the nerves supplying trophic function to the teeth. If, then, Brown-Séquard was right, we must expect the offspring to reproduce these organs (the teeth) in a degenerate or diminished condition—possibly in a condition of lowered resistance to the attacks of caries." We presume that Dr. Pickerill feels that the question of heredity remains quite obscure. Dr. Waller's paper is devoted to the question of the influence of insufficiency of the thyroid gland upon dental caries. He considers that it is unwarrantable to assume that the disease is merely a question of diet, and in his opinion the presence or absence of caries is due to the alkalinity of the saliva, and this is intimately associated with the effect of the thyroid gland on calcium metabolism. The increased thyroid activity, he considers, either causes increased elimination of calcium or perhaps by interaction with other ductless glands prevents the proper assimilation of calcium, and so, by leading to defective alkalinity of the saliva, permits the occurrence of dental caries. The increased thyroid activity he attributes to brain work. Both these papers are interesting but inconclusive.

THE King has granted Dr. George Ernest Morrison, Political Adviser to the President of the Republic of China, authority to wear the Insignia of the First Class of the Order of the Excellent Crop, which decoration has been conferred upon him by the President in recognition of valuable services.

BRITISH NEOSALVARSAN.—Messrs. Burroughs Wellcome and Co. have obtained a licence from the Board of Trade for the manufacture of neosalvasan. After passing biological tests under arrangements approved by the Board of Trade, this product is now being issued under the name of "Neokharsivan" brand neosalvarsan. For "Neokharsivan" there is claimed the same advantages over salvarsan that are claimed for neosalvarsan of German manufacture, and it is employed in the same manner and dosage. There are six strengths, 0·15 grm., 0·3 grm., 0·45 grm., 0·6 grm., 0·75 grm., and 0·9 grm., each dose being issued in a hermetically sealed tube. The supplies are for the moment limited, but the manufacturers state that they will soon be able to cope with the demand.

FACIAL PLASTIC SURGERY, LARYNGOLOGY, AND STOMATOLOGY, IN FRENCH MILITARY HOSPITALS.

Impressions de Voyage.

BY J. DUNDAS GRANT, M.A., M.D. EDIN., F.R.C.S. ENG.,

AURIST AND LARYNGOLOGIST TO KING GEORGE HOSPITAL, LORD KNUTSFORD'S SPECIAL HOSPITAL FOR OFFICERS, ETC.; LATE MAJOR R.A.M.C., POST-OFFICE RIFLES VOLUNTEERS.

HAVING recently had occasion to go to Paris and Bordeaux I was afforded the opportunity, by the courtesy of some of my medical friends, of visiting certain of the military hospitals. I wished mainly to acquaint myself with the results of wounds and other influences of warfare on the throat, nose, and ear. At the Hospital of the Val-de-Grâce my friend Dr. Luc kindly introduced me to the "service" of M. Morestin for the treatment of wounds of the nose and face in general. This was to me so striking that I described it to several of my surgical friends on my return, and my superficial report seemed to them so interesting and in some ways so new that I venture to draw attention to it in these few lines. I have no doubt that the same kind of work may be carried out in our home military hospitals, but I scarcely think that any approach to such an accumulation of material of the kind at any one place could be found there. Apparently the bulk of such cases are drafted into this "special" department from a very extensive part of France. In any case there were wards full of soldiers with ghastly disfigurements of the face resulting from rifle or shrapnel bullets or the fragments of shells or grenades. These seem to have been more frequent since the fighting has been mainly carried on in the trenches, where naturally the head and face are the parts of the body most likely to be exposed.

Every possible disfigurement was seen in multiple, but some of the most characteristic were those involving a driving in of the bridge of the nose, leaving the tip turned up "en lorgnon," and complete occlusion of the deeper nasal passages. The associated lacerations produced with this an aspect of the utmost repulsiveness. In these cases M. Morestin adopted a method of operating in stages, which seemed to me to present some original features. The first step is the detachment of the remainder of the nose from above downwards by a transverse horseshoe incision, extending nearly to the naso-labial folds on each side, forming a flap attached below and containing the tip of the nose and anterior nares. This leaves raw surfaces round a somewhat piriform orifice inside which the remains of the septum and nasal contents may be traced in a mass of débris and cicatricial tissue. The passages of the nose are cleared and the open cavity stuffed with gauze to prevent readhesion. In a few days the gauze is replaced by indiarubber tubes or bands with leaden weights attached so as to keep the flap down. Another step is to implant in the forehead a portion of cartilage from a false rib, and when this has taken root a new nose is formed in the classical manner by means of a flap from the forehead in which is included the piece of cartilage. Patients with this operation in all its various stages were to be seen in these wards or walking about in the grounds. Naturally the plastic surgery of the face in every form is carried out, but the cases I have referred to seemed to be of special interest.

At Talence, near Bordeaux, there is a large hospital which forms a centre to which "special" cases are sent. Here nearly one-third of the beds are apportioned to the department of oto-rhino-laryngology for the 18th Region, under Dr. E. J. Moure, the specialist who is so well known as the adviser of the King of Spain. His work, of course, overflows far beyond the ordinary routine of civil practice, and includes a large amount of plastic surgery as well as the removal of portions of projectiles or the treatment of their effects. He makes frequent use of the extra access afforded by surgical detachment and elevation of the ala nasi for the clearance of passages through the nose and the replacement of distorted alæ. A specially interesting part of his work is the treatment of traumatic stenoses of the larynx by the operation of laryngostomy. This is more readily carried out in the adult than in the child, and has been found of great value. The plastic surgery of the face is also illustrated at Talence by a large number of cases under the care of Dr. Dubreuilh.

Among the most striking types of cases to be seen here are those of extensive destruction of the lower jaw. In these we have the disfigurement accompanied by masticatory, articulatory, and salivary trouble; the sufferers unable to take solid food, incapable of intelligible utterance, dribbling and disfigured, present a most woeful appearance. The extraordinary feature is that in spite of all they seem full of the patience, cheerfulness, and buoyancy in the midst of their trouble, which is characteristic of the French soldier. The cheering side of this depressing picture to the medical visitor is the remarkable resourcefulness and keenness of the dental surgeons in the "Service de Stomatologie." I am informed that the science and practice of dentistry are practised with exceptional ardour in the south of France. At all events the Service of Stomatology is a scene of the greatest activity. Most cases of fractured jaw are X rayed, photographed, modelled in plaster, drawn and painted by workers in military uniform, who seem to give of their best, with all their hearts, in return for their exemption from the sterner work of the field. The main idea is, of course, to patch up the mandible, but in such a way as to ensure coaptation with the maxilla and secure the "bite." There is nothing the military stomatologist seems to resent more than union attempted by means of a wire suture. A cast is taken of the upper jaw and then of the lower one as a whole or often in parts. Metal collars are adapted round the teeth and by their means screw apparatuses are attached for pressing the fragments asunder if they override, or elastics for drawing an outwardly displaced fragment in towards the middle line. Inclined planes ("buttoirs") formed of gilded metal are often used with the same object. The ultimate adaptation of a prothesis with artificial teeth is the main end from the physiological point of view and no doubt it is often attained. The benefit from the æsthetic aspect is also unquestionable. Our own dental surgeons are not at all likely to be behindhand in this class of work, but the hasty glance of the stomatological activity exercised at Talence impressed me with the importance of the dentist's work and of the lofty position it should hold in our scheme of care for the wounded, which I had not hitherto realised. It is only to be desired that every encouragement should be given to our stomatological colleagues on the part of the authorities, fellow surgeons, and money providers. They will require much room, much mechanical assistance, and much material, including metal both precious and other.

The enormous number of French in the field has, of course, provided an amount of material such as we—perhaps happily—are unable to command; and *the agmination of cases of special character in "centres"* allows of a concentrated study of their nature and requirements such as we can scarcely obtain at home. I cannot help thinking that a visit to one or more of the "centres" in France in a somewhat less casual way than my recent one was made, would be of interest and possibly of profit to those who have to deal with the wounded man for decoration as well as repair.

Cavendish-square, W.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Water-supply of Londonderry.

IT is satisfactory to be able to report that Londonderry is at last waking up to the importance of obtaining a really adequate water-supply. At a meeting of the corporation, held on April 20th, the city surveyor submitted a report, in which he recommended the adoption of a scheme for bringing water from Banagher Glen, a place that is the junction of three rivers, which here unite to form the Owenrigh, a tributary of the River Roe. Of the 6000 acres proposed to be utilised, there are only 174 acres of arable and grass land, and of this only 100 acres are under cultivation, the remaining 5826 acres being all mountain upland. The quality of the water and the geological conditions have been reported as most satisfactory, and the quantity of the water would be quadruple that of the present supply. The elevation is sufficient to send this water into the present reservoirs, and it is estimated that the scheme (including filtration and an aqueduct across the river Foyle) would cost about £209,000. It has been arranged that the corporation of Londonderry in a body shall inspect the site.

The Alcohol Question.

Some of the Belfast papers have published references to an interesting article by the late Dr. Thomas Andrews, F.R.S.—the distinguished chemist who did such original work in the liquefaction of gases, and who for many years was Vice-President of Queen's College, Belfast. The paper is called Suggestions for Checking the Hurtful Use of Alcoholic Beverages by the Working Classes, and was contributed to the annual meeting of the Social Science Association, which met in Belfast in 1867. In this communication Dr. Andrews recommended that no house should be licensed as a public-house for the sale of alcoholic beverages unless it be provided with ample appliances for cooking and serving food; that the licence should be withdrawn if it be found that these appliances are not made use of and that the public-house is devoted solely to the sale of stimulants; and that no licensed publican should be allowed to sell, or keep in store, any liquor containing more than 17 per cent. of alcohol.

The King Edward Memorial in Belfast.

The Executive Committee decided unanimously, at a meeting on April 23rd, to request the Lord Mayor of Belfast, who presided, to invite the Lord Lieutenant of Ireland to open the King Edward memorial buildings at the Royal Victoria Hospital, Belfast, during his coming visit next month. Owing to the war the special laboratories (X ray, vaccine-therapy, and bio-chemical) are not yet fully equipped, and it was agreed to defer their inauguration until a future date.

PARIS.

(FROM OUR OWN CORRESPONDENT.)

Rice Flour in Bread-Making.

WITH a view to augmenting the national supply of breadstuffs, Dr. Maurel has brought to the notice of the Académie de Médecine the use of a mixture of 20 per cent. of rice flour with 80 per cent. of wheat flour. The mixture is free from hygienic objections and gives a bread presenting nutritive qualities equivalent to those of all-wheat flour. The bread thus prepared is of good appearance and taste and it is rather less in price. Another important advantage lies in the fact that France would thus find in the supplies of rice from Cochin China all that is necessary to balance any future deficiency in the wheat-supply. It should be further noted that scientific methods make it possible easily to determine the proportion of rice flour in the mixture, thus establishing a check on fraud. The country would find a great economic gain in adopting this use of rice, for a million tons of rice flour at 27 francs the metric quintal would cost France only 270 millions of francs, whilst a million tons of wheat flour would cost 420 millions. All that would be necessary would be that the Government should authorise the mixture, so that it would not be penalised as fraudulent.

Rapid Cicatrisation of Atonic Wounds by Biokinetic Measures and Intermittent Dressings.

Wounds occurring in war, if without bone lesions, ordinarily heal very quickly under established methods of treatment, such as dressings of iodine, oxygenated or boiled water, or dry gauze, each method having its special indications and advantages. There are, however, certain kinds of wounds which resist all these methods of treatment. M. François Debat recommends that in such cases every antiseptic of whatever kind should be dispensed with. At first a soft dressing should be applied of fine gauze slightly moistened with saline solution and covered with a layer of cotton-wool. The wound, he says, should be exposed daily to the air for a period of exposure progressively increasing in proportion to the decrease of any oozing. On the first day it may be exposed for two hours, the duration ordinarily increasing by an hour a day. When there is no longer any oozing the saline solution may be replaced by the application of a thick paste of zinc oxide or "innotyol." Every hour the muscles underlying the wound should be exercised for five minutes, the limb being raised. Meanwhile the patient should keep his bed if the lesion is in the lower extremities; if in the arm he should wear it in a sling. Daily massage is also advised. This very simple method is said to bring about prompt cicatrisation of some obstinate wounds.

April 26th.

PRESENTATION TO LIEUTENANT-COLONEL E. J. JEROME (T.F.).—Lieutenant-Colonel Jerome was recently presented with a massive silver inscribed rose bowl as a mark of esteem on the occasion of his retiring from the 5th Devon and Cornwall Light Infantry (T.F.).

OPHTHALMOLOGICAL SOCIETY OF THE UNITED KINGDOM.

ANNUAL CONGRESS.

THE annual Congress of the Ophthalmological Society of the United Kingdom was held on Thursday, Friday, and Saturday, April 22nd to 24th, under the presidency of Mr. F. RICHARDSON CROSS, of Bristol. The discussions took place at the headquarters of the Royal Society of Medicine, and the clinical meeting at the Royal London Ophthalmic Hospital, City-road. There were two set discussions, one upon Ophthalmic Injuries in Warfare, introduced by Mr. W. H. H. JESSOP; and one on Detachment of the Retinæ, introduced by Mr. M. S. MAYOU. Some of the other contributions were of considerable interest.

Mr. CHARLES WRAY contributed a paper on

The Diagnosis and Treatment of Bony Tumours of the Orbit.

With regard to their removal, he contended that the figures of Herschfeld placed the subject in its true perspective. They showed that the mortality in cases of sinus growths—frontal, ethmoidal, and sphenoidal—was 48·2, 80, and 100 per cent. respectively; whilst the post-operative mortality was 13·6, 12·7, and 33 per cent. The two main methods of diagnosis were by palpation and the use of Roentgen rays. As examination by the fingers was too limited, he advised the use of a thin flexible spatula 10 mm. wide and 2 mm. thick at the ends. This, pressed on the skin under the supraorbital notch, passed 15 mm. under the lid, and *viâ* the fornix 33 mm.—i.e., within 12 or 13 mm. of the sphenoidal fissure. The measurements at the lower orbital margin were 12 and 16 mm. respectively, while at the inner and outer canthus the distance reached was 15 and 21, and 11 and 22 mm.; and as the usual distance from the margin of the orbit to the rectal spine was 45 mm. it was possible thus to investigate half the outer wall of the orbit. In the living subject it was desirable to administer morphia for an hour and deep injections of novocaine ten minutes before beginning the examination. With regard to the operation, he laid stress on the importance of dissecting up the superjacent membrane if present, and the periosteum, so as to shut off as efficiently as possible the field of operation from the contents of the orbit. Having tested the hardness of the growth, an attempt should be made to test the strength of the attachment to the bone, as slight leverage might snap the pedicle. If this did not occur and the tumour was cancellous it should be removed piecemeal, so as to discover its relation to the orbital wall. If originating from a subjacent sinus, and especially if hour-glass shaped, the bone should be cut away so as to allow of easy removal in the safest direction. Two important landmarks were the inner canthus (over the anterior extremity of the middle turbinated) and the anterior ethmoidal foramen (giving the level of the cribriform plate). Frontal sinus cases were the most frequent, and usually presented at the upper and inner part of the orbit. No operation should be undertaken in the presence of material alteration in the roof of the orbit as revealed by X rays. Ivory exostoses could not be removed piecemeal. As in the cancellous variety, gentle leverage was in order, and in the event of failure sufficient of the orbital wall should be cut away to permit of removal in the safest direction. A clue to the size and location of the growth was obtained by radiography and the use of a strong needle.

Mr. W. D. HARMER read a paper on

The Intranasal Treatment of Dacryocystitis.

As nasal inflammations and abnormalities rarely cause dacryocystitis, treatment of such conditions was generally disappointing. Intranasal operations on the tear sac or duct became popular in 1912, after the operations of West, Polyak, and Yankauer. A modified West operation had been preferred. Of 14 cases treated, 6 have been cured, 3 improved, 4 not improved and not traced. Operations were easy to perform and could be repeated if necessary. Dacryocystotomy was probably the best treatment for dacryocystitis.

Captain A. W. ORMOND read a paper on

Injuries to the Eye in Warfare.

He recounted three cases of traumatic amblyopia following the explosion of shells. The first was of a soldier who was in the retreat from Mons. He recovered entirely after complete rest and "feeding up." A second case was associated with an error of refraction which had led to the idea that recovery had not taken place; while the third had not yet regained his former sight, though wounded more than three months ago. It was pointed out how difficult these cases were to diagnose, and how important it was to take the psychology of the men into consideration. He described the frequency of "explosion injuries" peculiar to the war, the result of hand grenades, shrapnel, or high-velocity shells. Numerous cases had occurred in which, as the result of a general explosion, small fragments of metal or dirt had been forced through the tunics of the eye. These had sometimes been overlooked, and later on, the man having complained of pain and inflammation, iritis had been correctly diagnosed, but the possibility of a foreign body being in the eye had not been realised, and sympathetic trouble might have occurred. He related two cases in which the speedy removal of the eye prevented sympathetic trouble supervening. With regard to the vexed question of removing an eye containing a foreign body, he recommended that no general dogmatic statement should be made on this debatable point, as each case must be separately considered. He deprecated relying solely on the findings of X ray examination, because in several cases the foreign body was not discovered until a second or third radiogram had been taken, and sometimes not even then. The history, the nature of the inflammation if any, and the amount of vision should be taken into consideration when making a decision. Short notes were given of 28 blinded soldiers, most of whom were now at St. Dunstan's, Regent's Park. Thirteen of them have no perception of light at all, and the sight of those with vision ranged from mere perception of light to ability to count fingers in one part of their field. Eighteen were the victims of bullet wounds, which for the most part traversed the front part of the head from side to side; 4 were wounded by shrapnel, 1 by a hand-grenade, and the others by explosion, the exact nature of which the men did not know. One, however, was due to a bullet hitting the magazine of the man's own rifle, which exploded in his face. Captain Ormond said that several of the men when looked at appeared absolutely fit, often with both eyes intact, the scars of entrance and exit wounds being almost impossible to locate.

Mr. CYRIL H. WALKER read a paper describing

Cure of Spontaneous Detachment of Retina by Multiple Scleral Puncture.

The patient, aged 39, had sudden loss of sight in part of the right field in September, 1901. Two days after the occurrence there was a large detachment above, the summit of which was estimated as +12 D. He had 4·5 of myopia. He was ordered complete rest in bed for a week, and then was allowed up for an hour a day The detachment had now swung round to the lower part of the eye, with corresponding change in the field; vision had improved. A further fortnight of partial rest again showed improvement, and he was allowed out; but the sight rapidly got worse and the detachment increased. Improvement followed more rest in bed, but it was only temporary; in December the vision had fallen to 6/60. He was ordered to bed again, and five scleral punctures with a discission needle were made 10 mm. from the lower border of the cornea. The retina was pierced at each puncture, and the needle was rotated 90° after the last puncture to let out some of the subretinal fluid under the conjunctiva. On Dec. 21st the sight was immensely improved, and he resumed full work on March 4th, 1902, with vision 6/6 with glasses and a normal field. The condition had been maintained ever since, and the only sign of detachment was the presence of a little pigment below in the choroid.

Mr. M. S. MAYOU read a paper on a case of

Retinitis Pigmentosa treated by Trephining,

the improvement following which had been maintained for four and a half months, in the hope that some light might be thrown on the etiology of a little understood disease. In this condition anything which improved the retinal circulation would temporarily benefit vision—such as amyl nitrate or paracentesis of the anterior chamber. Doyne had shown that extraction of the lens was followed by immense improvement in vision due, it was considered, to the fact that the patient was always in a condition of semi-daylight owing to the cataract, so that the retina did not receive sufficient stimulation. Mr. Mayou, while not denying this, thought that the lowering of the intraocular tension, with the consequent flushing of retinal vessels, and the filtration of fluid through the scar, might be an additional factor, possibly the most important one, in the good result. He (Mr. Mayou) thought trephining would result in the retinal vessels being flushed with blood, and that the subsequent leakage might lead to a more rapid excretion of fluid from the eye and drain away any toxic products which might be causing local vascular sclerosis. The patient was a female, aged 17, who for two years had complained of night-blindness. Grandfather, father, one paternal aunt, and one brother were all affected with the same disease. The four sisters of the patient were not night-blind. She showed marked pigmentation of the periphery, the discs being slightly grey in colour and the vessels of practically normal size. The lenses were clear. When first examined the fields were contracted to a 10° circle on both sides. On Nov. 13th last and again on Dec. 1st paracentesis of the left eye was performed, and on each occasion there was distinct improvement in the fields. On Dec. 8th trephining was done under general anæsthesia. On removing the disc of sclera there was a very free prolapse of iris, and it was slightly caught in the wound; recovery was otherwise uneventful. A week later the field on this side had practically reverted to normal, and she could walk about freely in a darkened room. Improvement was maintained to the present date. On covering the unoperated eye she could see well at night time, but if both eyes were open she was still somewhat night-blind. He could not advance any explanation of this. The improvement could not be expected to last very long, but it might continue for a length of time which justified the operation in selected cases.

Mr. F. A. JULER read notes of a case of

Papilloma Removed from the Upper Canaliculus.

The tumour came away, after slitting the canaliculus, quite easily; there was no apparent pedicle. It measured 10 by 4·5 mm., and in structure was a papilloma with stratified epithelium.

Dr. GEORGE MACKAY (Edinburgh) read a short note on a case of

Lymphangioma of the Orbit with Hæmorrhages.

The patient was seen first in 1906, being then 15 months old. Paracentesis and, later, excision so far as practicable having failed to eradicate the growth from the apex of the orbit, X ray treatment, given by Dr. Hope Fowler, had been employed, and with much benefit. Owing to the irregularity in the patient's attendances proptosis had been allowed to recur at intervals of one to three years, but had always yielded to further X ray applications. The cure now appeared to be complete and vision and movements were unimpaired.

Choroid and Retina of the Fruit-Bat.

Mr. GEORGE COATS demonstrated a peculiarity of structure in the choroid of the fruit-bat which was first observed by Lindsay Johnson. Instead of being smooth the surface is covered with innumerable conical prominences, each containing a central vessel which projects from the apex in the form of a long capillary loop. The outer surface of the retina has a similar serrated sectional outline. The condition is not found in any of the insectivorous bats, whose eyes in other respects also are inferior in development. It had been suggested that the structure was a device for the nourishment of the retina, in which central retinal vessels are absent in the bat. But many animals—e.g., the elephant and rhinoceros—which have a much thicker and more extensive retina have also no, or only rudimentary, central vessels; yet their retinæ obtain sufficient nourishment from a flat choroid without the sacrifice of form vision which the arrangement in the fruit-bat necessarily entails. According to another hypothesis the structure is an accommodative mechanism, images of distant objects falling on the most anterior plane of the serrations; of near objects on the most posterior. Evidence was adduced to show that the range of accommodation so obtained could not be great, and that, inasmuch as the formation of a clear image was impossible, it could not be very useful. The most probable explanation was that the condition was a device to enable the eye to make the best possible use of low illuminations. Evidently the serrated contour of the retina must greatly increase the superficies of the sensitive film and augment the number of visual elements concentrated within a given area. In other respects also—its relatively large size and the structure of the retina—the eye of the fruit-bat is characteristically adapted to a nocturnal habit.

Parasites in Eyelid and Anterior Chamber in Animals.

Mr. COATS also demonstrated an Encysted Nematode Parasite in the Eyelid of the Mouse. Professor A. E. Shipley considered it to be the Ollulanus tricuspis, the adult form of which occurs in the alimentary canal of the cat.

Lieutenant-Colonel W. G. PRIDMORE, I.M.S., and Mr. COATS demonstrated a Filaria from the Anterior Chamber of the Horse, probably an immature male of Filaria equina.

Discussion on Ophthalmic Injuries in Warfare.

Mr. WALTER H. H. JESSOP, in opening the discussion on this subject, dealt chiefly with the cases of injury in the present war seen by him at St. Bartholomew's and No. 1 Base Hospitals. He said that the steel or cupro-nickel mantle of the bullet was often chipped, and a fragment might perforate the cornea or embed itself in its substance. The initial high velocity of the bullet might be lost by ricocheting from a stone, and he had found that wounds so produced were more serious than direct ones. As most of the fighting was in trenches there was a greater proportion than usual of head and face injuries, as they were the parts most exposed to the enemy. There had been a few instances of spent bullets entering the orbit and remaining there without bursting the eyeball; they were probably ricochet. Such cases often showed intraocular hæmorrhages, choroido-retinal changes, and detachment of retina, generally complete. The most distressing ocular injuries, usually caused by enfilading fire, were those in which the bullet passed transversely through both orbits. There must already have been at least 50 such cases. If it was found that a wound had been made in the orbital roof the brain substance would fill it up; and as sepsis could not be prevented it was better to leave well alone. When the orbit and eyeball were much damaged it was better to foment the wound and keep it as clean as possible with sodium chloride solution, delaying removal of the eyeball until the conditions were less inflamed, always having in mind the risk of sympathetic ophthalmitis if the other eye were a good one. In the case of both eyes being destroyed, it was better to wait until the danger of sepsis was over, or it was much reduced, before removing the destroyed eyeballs, owing to the fear of meningitis. He described an operation devised by Mr. W. T. Lister to avoid the opening of the nerve sheath. Eyelid injuries he found to be very common, and almost always accompanied by injuries of the eyeball. Usually the lids became very œdematous, hence sutures should not be inserted into them. Conjunctivitis did not seem to have been prevalent in this war. In the Franco-German War 55 per cent. of cases of eyeball injury developed sympathetic ophthalmitis; in the American Civil War the percentage was 16·14. In the present war he had not seen or heard of a single case of the kind, which he attributed to the great care exercised in diagnosis and treatment, and especially the early enucleation of a ruptured globe. He had only seen one case of bullet wound implicating ocular nerves, and that he described; it was a ricochet bullet. The bullet and shrapnel wounds of the skull vault were generally depressed, and there was a great frequency of papillœdema in such cases; the appearances were those due to pressure. Papillœdema was probably present in all cases of vault injuries, with increased intracranial pressure; it was not usually seen when this pressure remained normal. Fractures of the skull near the occipital lobes were often accompanied by hemianopsia. At the beginning of the war there were many cases of complete blindness following severe explosions; but sight returned at different periods up to a week. The condition in these cases was always bilateral. Some cases were deaf. In rarer cases the patient was dumb. Three of the men had extreme blepharospasm, so that they could not open their eyes for days. The initial shock in these cases was loss of consciousness, which, passing off, left loss of sight, deafness, or even loss of speech, all temporary.

Mr. W. T. **LISTER** said the outstanding features of the ophthalmic injuries in the present war were their severity and the impossibility, in most cases, of employing conservative surgery. Still, there was a great deal of work to be done. He grouped the cases into the following classes: contusions, wounds, cases with foreign body in the eye, functional cases, and head cases. These he considered seriatim. In concussion cases, if the bullet did not go through the orbit the fundus showed no concussion changes. Ruptures of the choroid were fairly common, and they might be starlike or arranged in definite groups. The rest of the retina showed some pallor due to *commotio retinæ*. Cases of penetration of the eye by small foreign bodies formed a very unsatisfactory group to deal with. Many of the particles did not give a sensible X ray shadow, and even if they did many of the fragments were non-magnetic. Two factors increased the poor outlook in operation: (1) the frequent presence of more foreign bodies than had been diagnosed; (2) the friability of the foreign bodies, so that they broke off when caught in the forceps. It was difficult to know what to do in the case of a foreign body in the eye when the sight remained useful. He believed that even if an eye contained a foreign body, if there were no prolapse or entanglement of the uvea or lens capsule, the risk of sympathetic ophthalmitis was *nil*. Though the eye would probably degenerate, useful vision might persist for a considerable time. If signs of irritation did not abate, he would remove the eye. Foreign bodies in the cornea were often very troublesome to remove. When the foreign body was deeply embedded, he found a Beer's knife most useful. Mr. Lister went on to discuss in some detail functional cases, and quoted some striking instances. In head injuries, papillœdema occurred in slightly over 50 per cent. of the cases, but two-thirds of these had merely blurring or slight swelling. The greatest swelling occurred in association with cerebellar abscess. He did not attach much diagnostic importance to hæmorrhages or exudations; and the presence of papillœdema did not point to the immediate necessity of operation; it was increasing swelling which was the significant factor. He regarded cases of occipital injury as of very great interest, as a study of them might cast important light on the cortical representation of the fundus. The facts arrived at by Dr. Gordon Holmes and himself, from the examination of a number of cases, were: (1) when the lesion occurred over the occipital cortex of only one side, the result was either hemianopsia, or homonymous quadrantic defect on the opposite side; (2) when the bullet passed through both occipital lobes, there was at first complete blindness, but in several cases this gradually cleared centripetally after an interval varying from hours to days, leaving a central scotoma. Mr. Lister regretted that his observations were not fuller, but reminded his hearers that cases were after a short time sent over to England.

The discussion was continued by Mr. **TREACHER COLLINS**, Mr. P. H. **ADAMS**, Mr. G. H. **POOLEY** (Sheffield), Mr. L. V. **CARGILL**, Mr. **MACKAY**, Mr. R. R. **CRUISE**, Mr. F. **THOMAS**, Mr. A. L. **WHITEHEAD** (Leeds), Mr. **PRIESTLEY SMITH** (Birmingham), Mr. M. M. **TOWNSEND**, Colonel **ELLIOTT**, Mr. J. **GRAY CLEGG**, Professor **LANDOLT**, and the **PRESIDENT**.

At this siting the Nettleship medal and prize were presented to Mr. Treacher Collins for his valuable work in the specialty.

(*To be continued.*)

ROYAL ABERDEEN HOSPITAL FOR SICK CHILDREN.—The thirty-eighth annual report (1914) states that 2945 cases were treated during the year, 888 as in-patients and 2057 as out-patients. Of these, 687 were discharged as cured, 111 died, and 45 were still in the wards at the close of the year. The remainder were removed as unfit, &c. The expenditure exceeded the income by £529 12*s.* 8½*d.* The sum of £980 19*s.* 5*d.* had been received in legacies during the year. The income for the year is slightly augmented, the city collections showing an increase of £41, the collection from the county parishes being increased by £253 17*s.* 11*d.* as compared with 1913. The building fund for the new hospital had increased during the year by £1773 2*s.* 4*d.* The total amount to the credit of the fund was now £12,498 1*s.* 3*d.* This sum, together with what was promised and payable, £8313 10*s.*, was still far short of the estimated cost of the new hospital.

THE SERVICES.

ROYAL NAVY MEDICAL SERVICE.

THE undermentioned have been granted temporary commissions as Surgeons:—Dallas Scott Falconer, Walter Ethard Goss, William Sloane Lynd, and John Scott Kennedy.

The following appointments have been notified:—Fleet-Surgeon: R. S. Bernard to the *Victory*. Staff-Surgeon: W. P. Hingston to the *Vivid*, additional. Surgeons: H. E. R. Stephens to the *Lion*; J. A. Russell-Cargill (temporary) to the *Victory*, additional, for R.N. Division, Crystal Palace; R. A. Rankine to the *Pembroke*; and K. H. Hole to the *Thames*. Temporary Surgeons: T. D. Power to the *Zealandia*; E. W. Todd to the *St. George*; and N. N. Wade to the *Ganges*, additional, for Shotley, R.N. Sick Quarters.

ROYAL ARMY MEDICAL CORPS.

The undermentioned to be temporary Captains:—Dated April 1st: Thomas Henry Rickard Crowle and Gordon Taylor.

The undermentioned to be temporary Lieutenants: Dated Oct. 24th, 1914: Alfred John Andrew. Dated Feb. 7th: Harold Victor Lamb. Dated March 2nd: Arthur John Wilson Compton. Dated March 26th: Newman Smith, John Bowman Hunter, and Arnold Renshaw. Dated March 28th: Gwilym Rhys Pennant, Thomas William David, and Guy William Parry. Dated March 29th: George William FitzHenry and Meilor Bridgman. Dated March 30th: Percy Wilkes Leopold Camps. Dated April 1st: Ian Mount Grant, John Oscar Thomas, Benjamin Theodore Saunders, Guy Berners Nicholson, Arthur Russel Rendle, George Donaldson Fairley, Thomas Baxter Carlyon, Edward Maurice Hime, William Henry Sheffield, Duncan Wood, Frederick William Woods, John Keay, Kenneth Harrison Alloa Kellie, William Gilbertson, Ernest Clarkson Bourdas, Ernest Percy Satchell, Henry St. Arnaud Agate, Howell Wood Barnes, John Henry Joseph Davys, John Paton, John Moffat Logie, James Norman Wheeler, Karl Frederick Sonntag, Hans Anthony Conrad Swertz, John Bell Walker, Harold John de Brent, Arthur Dashwood Howard, Percy Kitchen, Philip Heywood Hadfield, John Craven Glen, David Gillies, Arthur Emery, James Browning Alexander, Reginald Williams, Charles Edward Bashall, Charles Allen Robinson, John Patrick Howe, Herbert Henry Folker, Leslie Herbert Walsh, Frank Bryan, Charles Calthorp de Burgh Daly, Benjamin Hilton Leigh, Sidney Campbell Dyke, William Newton Parker, Thomas William Kelly, William Benjamin Heywood, Robert Alexander Flynn, William Beck, Eric Reginald Delme Maconochie, Charles John Gibson, Edward Ferdinand Greene, Ernest Saxton, Sidney Herbert Hall, Frederick Guy Bullmore, Hubert Redmayne Sedgwick, Ernest Allan, John Donald Gunn, David Charteris Graham, Robert Linton Ritchie, Emanuel Mary Joseph O'Farrell, William Charles Watson Glenny, James Alexander Gentle, John Marchant Fry, John Cecil Rix, George Warwick Deeping, William Hutchison, and John Wylie. Dated April 2nd: Robert McCheyne Paterson, Walter Haward, Bernard Score Browne, Charles Butler, Robert Moore, Andrew Ferguson Horn, Robert Denman, John Desmond Gimlette, Ernest Richard Stone, Charles Ewart Dashwood, William Douglas Wilkins, and William Harvey. Dated April 3rd: Harold Bourne Taylor, Henry Brooke Shepherd, William Bertram Lawrence, James Craig, Andrew Hardie MacKenzie, Philip Augustine McCarthy, William Arnison Slater, and Harry Grey. Dated April 5th: Edwin William Sidney Martin. Dated April 6th: Donald Fisher, William John Francis Symons, Richard Albert Banbury, John Connell, James Benjamin Hoghton Davson, Thomas Johnston, Ambrose Pode Yonge, William John Hill, Arthur George Southcombe, Wilfred Vedal Robinson, John Henry Sheldon, and Evan John Goronwy Jones.

SPECIAL RESERVE OF OFFICERS.

Royal Army Medical Corps.

The undermentioned to be Lieutenants (on probation):—Frederick Ernest Feilden and Neville Hood Linzee, ex-Cadet of the Officers Training Corps.

TERRITORIAL FORCE.

Army Medical Services.

Lieutenant-Colonel Ernest O. Wright, from Deputy Assistant Director of Medical Services, Home Counties Division, to be Assistant Director of Medical Services, West Riding Division, with the rank of Colonel.

Royal Army Medical Corps.

London Mounted Brigade Field Ambulance: Private Ronald Douglas Stuart Mar, Lord Cardross (late Lieutenant, Scots Guards), to be Transport Officer, with the honorary rank of Lieutenant.

1st London (City of London) Field Ambulance: Captain Andrew Elliot to be temporary Major. Lieutenant Arthur D. J. B. Williams to be Captain, and to remain seconded.

2nd Highland Field Ambulance: Benjamin James Alcock to be Lieutenant.

2nd London (City of London) Field Ambulance: Arthur Hardwicke Platt to be Lieutenant.

2nd Northumbrian Field Ambulance: John McDonald Nicoll (late Major, 7th Battalion, The Durham Light Infantry), to be Major (temporary).

3rd Welsh Field Ambulance: John Evans (late Captain, 6th Battalion, The Royal Welsh Fusiliers) to be Major (temporary). John William Dale to be Lieutenant.

1st Eastern General Hospital: Lieutenant Ffrangcon Roberts, from 1st East Anglian Field Ambulance, to be Lieutenant.

4th London General Hospital: George Arthur Ewart to be Captain, whose services will be available on mobilisation. Captain William Hunter is seconded.

1st Northern General Hospital: Stuart McDonald (late Captain, Unattached List for the Territorial Force), to be Captain, whose services will be available on mobilisation.

1st Scottish General Hospital: Major Henry McI. W. Gray is seconded. Captain Middleton Connon, from Sanitary Service, to be Captain, whose services will be available on mobilisation.

1st Southern General Hospital: Bertram Arthur Lloyd to be Captain, whose services will be available on mobilisation.

3rd Western General Hospital: To be Lieutenants: Lieutenant Ivor J. Davies, from 2nd Welsh Field Ambulance, and Thomas Rufus Bowen.

2nd London Sanitary Company: To be Lieutenants: Herbert Beeney and Frederick John James Ney.

East Anglian Casualty Clearing Station: Frederick William Lewis to be Lieutenant.

Welsh Border Mounted Brigade Field Ambulance: John Arthur Eyton-Jones (late Surgeon-Lieutenant, 1st Volunteer Battalion, Royal Welsh Fusiliers) to be Captain (temporary).

2nd East Lancashire Field Ambulance: William Clegg-Newton to be Lieutenant.

2nd London Casualty Clearing Station: Athelstan Jasper Blaxland to be Captain (temporary).

1st Southern General Hospital: Captain Frank D. Marsh is seconded.

2nd Southern General Hospital: Major James Swain is seconded.

3rd East Lancashire Field Ambulance: William Calverley to be Lieutenant.

1st Northern General Hospital: Major Robert A. Bolam to be temporary Lieutenant-Colonel.

2nd Northern General Hospital: Major Sir Berkeley G. A. Moynihan is seconded.

2nd London (City of London) General Hospital:—The undermentioned officers are seconded: Major Sir Frederick S. Eve, Captain Sir William A. Lane, Bart., Captain Sir Bertrand E. Dawson, K.C.V.O., M.D.

3rd London General Hospital: Major Sir John R. Bradford, K.C.M.G., C.B., is seconded. Ernest Nevile Keys-Wells to be Captain, whose services will be available on mobilisation.

2nd North Midland Field Ambulance: Major John C. S. Burkitt, from Attached to Units other than Medical Units, to be Major (temporary).

1st Northern General Hospital: Captain George Hall to be Major, and to be seconded.

3rd Northern General Hospital: James Clark to be Captain, whose services will be available on mobilisation.

2nd Western General Hospital: Charles Paget Lapage (late Captain, Unattached List for the Territorial Force), to be Captain.

Northumbrian Casualty Clearing Station: William Albert Wetwan (late Major, 5th Battalion, Alexandra, Princess of Wales's Own (Yorkshire Regiment)) to be Major (temporary).

The undermentioned to be Lieutenants: Robert Wilkie Smith, Frederick Septimus Walker, Fred Phillips, and Stanley McCoull.

Attached to Units other than Medical Units.—To be Majors: Surgeon-Captain George Symers Mill, from the 4th Battalion, The King's Own (Yorkshire Light Infantry), Captain Henry W. Williams, and Captain John O. Summerhayes. To be Captains: Richard Timmis Turner (late Captain, 7th Battalion, The Cheshire Regiment), Lieutenant Horsley Drummond and Captain Arthur L. Yates (from the 4th Northern General Hospital). To be Lieutenants: John Macquarrie, Lieutenant Alistair Robertson Grant (from 2nd Highland Field Ambulance), Lieutenant Maurice U. Wilson (from the 5th London Field Ambulance), and Edward Stanley Johnson.

Territorial Force Reserve.

Royal Army Medical Corps.

Lieutenant-Colonel Arthur Lloyd Jones (late 3rd Welsh Field Ambulance) to be Lieutenant-Colonel.

Surgeon-General Robert W. S. Lyons, Indian Medical Service, has been appointed an Honorary Physician to the King, vice Brigade Surgeon-Lieutenant-Colonel (Honorary Colonel) D. D. Cunningham, C.I.E., deceased.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN the 96 English and Welsh towns with populations exceeding 50,000 persons at the last Census, 8809 births and 6063 deaths were registered during the week ended Saturday, April 24th. The annual rate of mortality in these towns, which had been 19·8, 19·9, and 19·0 per 1000 in the three preceding weeks, further declined in the week under notice to 17·4 per 1000 of their aggregate population, estimated at 18,134,239 persons at the middle of last year. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 19·6, against a corresponding rate of 20·6 per 1000 in London. Among the several towns the death-rate last week ranged from 6·8 in Barnsley, 7·0 in Darlington, 7·8 in Wallasey, 8·6 in Ilford, and 9·5 in Ealing, to 23·9 in Middlesbrough, 24·0 in Northampton, 24·5 in Hastings, 25·2 in Sunderland, and 28·1 in Dudley.

The 6063 deaths from all causes were 555 fewer than in the previous week, and included 689 which were referred to the principal epidemic diseases, against numbers declining from 826 to 736 in the three preceding weeks. Of these 689 deaths, 389 resulted from measles, 149 from whooping-cough, 65 from infantile diarrhœal diseases, 49 from diphtheria, 29 from scarlet fever, and 8 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·0, against 2·1 per 1000 in the previous week. The deaths attributed to measles, which had been 495, 452, and 426 in the three preceding weeks, further fell to 389 last week, and caused the highest annual death-rates of 3·4 in Sheffield, 4·4 in Stockton-on-Tees, 4·5 in Middlesbrough, 4·9 in West Hartlepool, 5·3 in West Bromwich, 6·6 in Coventry, 8·9 in Walsall, and 9·2 in Northampton. The deaths referred to whooping-cough, which had been 157, 167, and 151 in the three preceding weeks, fell to 149 last week, and included 52 in London, 13 in Liverpool, 9 in Leeds, 6 in Wigan, 5 in Hull, and 4 each in Stoke-on-Trent and Bradford. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 77, 67, and 63 in the three preceding weeks, were 65 last week, of which 18 occurred in London, and 4 each in Liverpool and Manchester. The deaths attributed to diphtheria, which had been 69, 49, and 55 in the three preceding weeks, fell to 49 last week; 15 deaths were recorded in London, 4 in Birmingham, and 3 each in West Ham, Northampton, Liverpool, and Leeds. The deaths referred to scarlet fever, which had been 16, 25, and 28 in the three preceding weeks, were 29 last week, and included 13 in London, and 2 each in Leyton, Liverpool, and Leeds. The fatal cases of enteric fever, which had been 12, 7, and 11 in the three preceding weeks, fell to 8 last week, of which 2 occurred in London.

The number of scarlet fever patients under treatment in the Metropolitan Asylums Hospitals and the London Fever Hospital, which had steadily declined from 5036 to 2422 in the 21 preceding weeks, had further decreased to 2369 on Saturday last; 259 new cases were admitted during the week, against 253, 275, and 263 in the three preceding weeks. These hospitals also contained on Saturday last 1251 cases of diphtheria, 377 of measles, 64 of enteric fever, and 14 of whooping-cough, but not one of small-pox. The 1619 deaths from all causes in London were 141 fewer than in the previous week, and corresponded to an annual death-rate of 18·7 per 1000. The deaths referred to diseases of the respiratory system, which had been 475, 466, and 469 in the three preceding weeks, fell to 392 in the week under notice, but were 134 in excess of the number registered in the corresponding week of last year. The deaths from influenza numbered 27, against 45, 46, and 39 in the three preceding weeks.

Of the 6063 deaths from all causes in the 96 towns 199 resulted from various forms of violence and 437 were the subject of coroners' inquests, while 1723 occurred in public institutions. The causes of 46, or 0·8 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest. All the causes of death were duly certified in Leeds, Bristol, West Ham, Bradford, Hull, Newcastle-on-Tyne, and in 62 other smaller towns. Of the 46 uncertified causes, 9 were registered in Birmingham, 3 each in Stoke-on-Trent, Dudley, and South Shields, and 2 each in London, Lincoln, Liverpool, and Southport.

HEALTH OF SCOTCH TOWNS.

In the 16 largest Scotch towns with an aggregate population estimated at 2,345,500 persons at the middle of this year, 1303 births and 938 deaths were registered during the week ended Saturday, April 17th. The annual rate of mortality in these towns, which had been 21·1, 22·1, and 20·8 per 1000 in the three preceding weeks, rose to 20·9 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged

22·4, against 19·6 per 1000 in the large English towns. Among the several towns the death-rate in the week under review ranged from 6·1 in Falkirk, 11·3 in Motherwell, and 14·7 in Perth, to 22·1 in Glasgow, 23·4 in Greenock, and 24·3 in Edinburgh.

The 938 deaths from all causes were 4 in excess of the number in the previous week, and included 133 which were referred to the principal epidemic diseases, against 181 and 154 in the two preceding weeks. Of these 133 deaths, 90 resulted from whooping-cough, 19 from measles, 10 from infantile diarrhœal diseases, and 7 each from scarlet fever and diphtheria, but not one from enteric fever or from small-pox. The annual death-rate from these diseases was equal to 3·0, against 2·1 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had been 81, 104, and 75 in the three preceding weeks, rose to 90 and included 47 in Glasgow, 16 in Edinburgh, 13 in Dundee, 4 in Greenock and 3 in Aberdeen. The deaths referred to measles, which had been 21, 45, and 41 in the three preceding weeks, fell to 19, and comprised 16 in Glasgow, 2 in Aberdeen, and 1 in Clydebank. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had increased from 5 to 18 in the five preceding weeks, fell to 10, of which 7 were registered in Glasgow. The deaths attributed to scarlet fever, which had been 12, 11, and 6 in the three preceding weeks, were 7 in the week under notice, and included 3 in Glasgow. The fatal cases of diphtheria, which had been 7, 6, and 11 in the three preceding weeks, fell to 7, of which 5 occurred in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 186, 162, and 182 in the three preceding weeks, slightly fell to 178 in the week under notice, but were 58 in excess of the number recorded in the corresponding week of last year. The deaths attributed to violence numbered 21, against 21 and 32 in the two preceding weeks.

In the 16 largest Scotch towns 1314 births and 834 deaths were registered during the week ended Saturday, April 24th. The annual rate of mortality in these towns, which had been 22·1, 20·8, and 20.9 per 1000 in the three preceding weeks, declined to 18·5 per 1000 in the week under notice. The rate in the several towns ranged from 10·2 in Kirkcaldy, 10·8 in Hamilton, and 11·7 in Clydebank, to 21·2 in Kilmarnock, 22·5 in Coatbridge, and 30·4 in Falkirk.

The 834 deaths from all causes were 104 fewer than in the previous week, and included 128 which were referred to the principal epidemic diseases, against numbers declining from 181 to 133 in the three preceding weeks. Of these 128 deaths, 75 resulted from whooping-cough, 26 from measles, 12 from infantile diarrhœal diseases, 7 from scarlet fever, 6 from diphtheria, and 2 from enteric fever, but not one from small-pox. The mean annual death-rate from these diseases was equal to 2·8, against 2·0 per 1000 in the large English towns. The deaths attributed to whooping-cough, which had been 104, 75, and 90 in the three preceding weeks, fell to 75 last week, and included 44 in Glasgow, 13 in Dundee, and 7 in Edinburgh. The deaths referred to measles, which had been 45, 41, and 19 in the three preceding weeks, rose to 26 last week, of which 20 occurred in Glasgow and 2 in Dundee. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 10, 18, and 10 in the three preceding weeks, rose to 12 last week, and included 6 in Glasgow and 2 in Aberdeen. The deaths attributed to scarlet fever, which had been 11, 6, and 7 in the three preceding weeks, were again 7 last week, of which 5 occurred in Glasgow. The deaths referred to diphtheria, which had been 6, 11, and 7 in the three preceding weeks, were 6 last week, and included 2 in Aberdeen. The 2 fatal cases of enteric fever were recorded in Glasgow.

The deaths referred to diseases of the respiratory system, which had been 162, 182, and 178 in the three preceding weeks, further fell to 145 in the week under notice, but were 15 in excess of the number in the corresponding week of last year. The deaths attributed to violence numbered 30, against 32 and 21 in the two preceding weeks.

HEALTH OF IRISH TOWNS.

In the 27 town districts of Ireland, with an aggregate population estimated at 1,212,380 persons at the middle of this year, 692 births and 521 deaths were registered during the week ended Saturday, April 24th. The annual rate of mortality in these towns, which had been 22·9, 23·8, and 22·1 per 1000 in the three preceding weeks, rose to 22·4 per 1000 in the week under notice. During the 13 weeks of last quarter the mean annual death-rate in these towns averaged 25·4, against corresponding rates of 19·6 and 22·4 per 1000 in the English and Scotch towns respectively. The death-rate last week was equal to 26·1 in Dublin (against 18·7 in London and 20·1 in Glasgow), 20·3 in Belfast, 23·1 in Cork, 22·8 in Londonderry, 16·2 in Limerick, and 15·2 in Waterford, while in the 21 smaller towns the mean death-rate was 20·9 per 1000.

The 521 deaths from all causes were 6 in excess of the number in the previous week, and included 41 which were referred to the principal epidemic diseases, against 40 and 30 in the two preceding weeks. Of these 41 deaths, 20 resulted from whooping-cough, 13 from measles, 5 from infantile diarrhœal diseases, 2 from scarlet fever, and 1 from diphtheria, but not one from enteric fever or from small-pox. The mean annual death-rate from these diseases was equal to 1·8, against corresponding rates of 2·0 and 2·8 per 1000 in the English and Scotch towns respectively. The deaths attributed to whooping-cough, which had been 13, 15, and 11 in the three preceding weeks, rose to 20 last week, and comprised 11 in Dublin, 7 in Belfast, and 2 in Londonderry. The deaths referred to measles, which had been 7, 16, and 5 in the three preceding weeks, rose to 13 last week, of which 6 occurred in Dublin, 5 in Portadown, and 2 in Belfast. The fatal cases of diarrhœa and enteritis (among infants under 2 years), which had been 11, 3, and 5 in the three preceding weeks, were again 5 last week, and included 2 each in Dublin and Belfast. The fatal cases of scarlet fever were recorded in Dublin and Waterford respectively, and that of diphtheria in Dublin.

The deaths referred to diseases of the respiratory system, which had been 121, 158, and 119 in the three preceding weeks, further declined to 104 in the week under notice. Of the 521 deaths from all causes, 148, or 28 per cent., occurred in public institutions, and 8 resulted from various forms of violence. The causes of 14, or 2·7 per cent., of the total deaths were not certified either by a registered medical practitioner or by a coroner after inquest; in the large English towns the proportion of uncertified causes did not exceed 0·8 per cent.

THE BELGIAN DOCTORS' AND PHARMACISTS' RELIEF FUND.

The progress of this Fund continues, but the outgoings for which preparation has to be made are now considerable. The Executive Committee, which is very sensible of the great generosity shown by the subscribers, wishes to point out that the work of relief undertaken by the Fund may be of long duration.

The Week's Subscriptions.

The subscriptions received by Dr. Des Vœux up to Tuesday evening last, in addition to those previously acknowledged, are as follows:—

	£	*s.*	*d.*
Association of Physicians of Great Britain and Ireland (per Dr. Hale White, Hon. Treasurer)	105	0	0
Nelson, New Zealand, District Doctors, Chemists, and Dentists	49	10	0
Societies of Medicine in Italy and Medical Men (per Professor Jacobs)	56	7	3
Dr. Barrs, Leeds, collected by—			
Dr. T. B. Hellier... ...	5	5	0
Dr. Rowden	2	2	0
Mr. Sydney Rumboll..	3	3	0
Dr. Frank E. Easton ...	3	3	0
Dr. R. M. Courtauld ...	2	2	0
South Indian Branch, B. M. A....	50	0	0
Southern Branch, B.M.A. (per Dr. Jas. Green, Hon. Sec.) (fifth donation — total £56 1*s.* 6*d.*)—			
Dr. A. Thomas	0	10	6
Dr. Henry S. Taylor...	1	1	0
Lt-Col. J. C. H. Peacocke	0	10	6
Dr. Francis E. Carey	5	0	0
Dr. S. Gaster	2	2	0
Bournemouth Division, B.M.A. (per Dr. E. C. Bond, Hon. Sec.) (third donation, total £121 2*s.* 6*d.*)—			
Dr. James Appleyard	1	1	0

"Audi alteram partem."

STOMACH *V.* HEART IN RELATION TO PRÆCORDIAL PAIN AND SUDDEN DEATH.

To the Editor of THE LANCET.

SIR,—In his ingenious and elaborate exposition of the symptoms exhibited in the patient, the subject of his letter to THE LANCET of April 3rd, Dr. H. Walter Verdon suggests the central nervous system as primarily responsible for them, and Dr. C. Edgar Lea, in describing his case in your issue of April 10th, whilst recognising the well-marked physical causes of the suffering, is still of opinion that there were hypersensitive nervous centres essentially concerned in the phenomena. I confess I am personally very sceptical as to segmentary neurosis being a causal factor of importance in angina pectoris, and I had thought that the purely neurosis view of its pathology had long been abandoned. There is, of course, no doubt as to the existence and in some degree the diagnostic value of localised "algesia," or, as I should prefer to say, surface pains, and points of tenderness in angina pectoris, as in association with most forms of visceral suffering, and a nerve centre may become hypersensitive from repeated excitation. The presence, however, in Dr. Verdon's case of commencing ossification, which must, I presume, stand for a marked degree of atheromatous rigidity, in the course of the coronary artery is, in my opinion, a very important factor in the pathology and issue of the interesting case which he describes. The symptom of pain over a præcordial area coming on during marked exertion, especially after a meal, is very common in aortic disease likely to eventuate in angina pectoris. The fact of its arrest on the cessation of effort strongly points to its being a pressure symptom in a tender vessel, as has been pointed out by Sir Clifford Allbutt. Very often the pain returns with the resumption of effort, and that it does not always do so is, I think, capable although difficult of explanation.

I am, Sir, yours faithfully,
R. DOUGLAS POWELL.

Portland-place, W., April 26th, 1915.

TREATMENT OF "INCRUSTED CYSTITIS" BY SUPRAPUBIC DRAIN AND INTRAVESICAL INJECTION OF LACTIC BACILLUS.

To the Editor of THE LANCET.

SIR,—My attention has been called to an address given to the American Association of Genito-urinary Surgeons at Stockbridge, Mass., on May 16th, 1914, by Dr. John R. Caulk, of Washington University Hospital, published in January of this year,[1] in which he says, in bringing the malady before the notice of the association, his object is "to emphasize its seeming malignancy if not properly treated, to outline some of its clinical and pathological features, and above all to present a treatment, which in my hands has worked not only satisfactorily, but like magic." The treatment consists of intravesical injection of lactic bacilli and suprapubic drainage, and in recommending the treatment he affirms: "As far as I have been able to determine, this procedure has never been previously used in incrusted cystitis."

The question of priority in adopting any particular treatment is of little importance as contrasted with a proper estimate of its real value. I am glad that Dr. Caulk has emphasised the usefulness of the lactic bacillus and drainage, in the treatment of cystitis, when there are phosphatic deposits in the bladder, a treatment I have used for more than a dozen years and found most valuable. In an article in THE LANCET,[2] in referring to the treatment of cystitis due to organisms which decompose urea, those which cause ammoniacal urine and the deposit of alkaline phosphates, I wrote:—

> When the urine is alkaline after irrigating an instillation of pure lactic bacillus cultures in milk whey or the filtrate of saurine may be employed with great advantage. By setting up an acid fermentation the urea-decomposing organisms are weakened or destroyed and the phosphates dissolved.

And with regard to suprapubic drainage—

> This drainage must be supplemented by careful irrigation, and if the urine is alkaline, or contains alkaline phosphates after irrigating, an instillation of lactic bacillus cultures should be given. Milk whey containing pure lactic bacillus not only destroys the septic organisms in the bladder but also dissolves phosphatic crusts adhering to the bladder or the wound. The filtrate of saurine does admirably and may be used with advantage in all purulent conditions. A suppurating sac or a granulating surface thoroughly washed regularly with it cleans up rapidly; it acts more satisfactorily than any chemical antiseptic, and the lactic acid bacillus not being a pathogenic organism does no harm. In some cases quite remarkable results have been obtained. …… The drainage employed is by syphoning the urine into a suitable vessel so as to permit the patient to go about with freedom. The method used for the last nine years is easily carried out and has been very successful.

It may be interesting for your readers to know that long before Metchnikoff discovered the value of the Bulgarian bacillus as a destroyer of smaller and less active organisms, in some parts of the Highlands of Scotland butter-milk was a common ingredient of poultices used for the cleansing of putrid sores. I first saw it used by a gamekeeper in the Island of Mull in 1893, and when he told me that the addition of butter-milk cleaned the sore immediately I was very sceptical, but when I saw the result a couple of days later I was more than surprised. Later in the same year an opportunity offered itself of testing the effect of poultices containing butter-milk, and the result satisfied me that there was something good in the treatment, as a sloughing surface, which was very putrid, soon cleared up, and the local irritation consequent on the septic absorption disappeared. Since then I have often used lactic bacilli cultures to destroy septic organisms. At a time when bacteriological research was in its infancy the simple filtrate of butter-milk, the whey, was used, but later pure cultures were made by inoculating sterilised solutions of sugar of milk with Bulgarian bacilli. Without or with a suprapubic opening I have used constantly this treatment of cystitis with most satisfactory results, and Dr. David Watson has employed a similar treatment for gonorrhœa in women.[3] In his admirable book on gonorrhœa he gives details of a method of preparing soft tablets and bougies, which are very convenient for his purpose, but I have always preferred freshly made cultures in a fluid medium as most suitable for urological work.

---

[3] David Watson: Gonorrhœa and its Consequences, 1914, p 265.

I have been unable to discover whether it is the lactic bacilli or their products that produce the effect. Chemically pure lactic acid dissolves phosphates, but it does not destroy septic organisms to anything like the same extent as freshly prepared cultures of lactic bacilli. I am inclined to believe that the lactic bacilli devour or break up the pyogenic organisms or their products neutralise the toxins of the less virile organisms. There is a bacterial contest takes place in which the lactic bacillus is always the victor. Recently I have used this treatment for the cystitis remaining after nephrectomy for tuberculous kidney. It certainly facilitates recovery in a remarkable way; but, of course, very special care must be taken to have the cultures pure.—I am, Sir, yours faithfully,

Glasgow, April 20th, 1915. DAVID NEWMAN.

THE MANUFACTURE OF SALVARSAN PRODUCTS IN ENGLAND AND FRANCE.

To the Editor of THE LANCET.

SIR,—In THE LANCET of April 3rd I described two cases of acute arsenical poisoning following injections of novarsenobenzol (Billon) and kharsivan (B. W. & Co.) respectively, and I shall be glad if you will allow me to supplement my previous letter by a brief description of two further cases following the use of one of the substitutes for salvarsan, one of which unfortunately proved fatal.

CASE 3.—A perfectly healthy youth, aged 19, was admitted to the Lock Hospital on Feb. 24th, suffering from a syphilitic sore and an early maculo-papular syphilide. On March 2nd he was given an intravenous injection of kharsivan 0·6 grm., which was not followed by any noticeable reaction. On March 11th a second injection of similar strength was administered, and on March 14th he developed intense and universal erythema, accompanied by extreme languor and irritation of the oral, naso-pharyngeal, and conjunctival mucous membranes, swelling of the eyelids, and photophobia. Subsequently there ensued a profuse exfoliative dermatitis, bronchitis, and broncho-pneumonia, to which condition he succumbed on April 12th.

CASE 4.—A strong, healthy man, suffering from early syphilis, received an injection of neosalvarsan (0·9 grm.) on Jan. 13th; on Jan. 18th he was given an injection of novarsenobenzol (0 9 grm.), and on Jan. 26th one of kharsivan (0·6 grm.). This treatment was followed by injections of "gray oil," and on Feb. 20th he was discharged free from symptoms. On March 6th he presented himself, suffering from an acute vesicular dermatitis, which, commencing in the pubic region, spread rapidly over the trunk, limbs, and face; this was followed by profuse desquamation, which is now subsiding (April 20th).

Thus, with the two cases mentioned in a previous communication, I have met with four cases of arsenical poisoning, since the beginning of the present year, following the employment of salvarsan substitutes, and in one of these cases I fear that this treatment must be held responsible for a fatal issue. In your issue of April 10th there appears a communication from the National Medical Research Committee on the manufacture of salvarsan products in England and France, from which it might be imagined that we are now perfectly independent of the German preparation. "The committee have caused experimental assurance to be obtained that both the French and English preparations are equivalent to the German in therapeutic effect. This has been done by a comparison of their relative potencies in curing experimental trypanosomiasis in mice, and experimental spirochæte infections in rabbits." These experimental researches on mice and rabbits may be perfectly satisfactory to the committee, but they are not in the least degree convincing to some who, like myself, are concerned in the treatment of the human subject. In an article in the *British Medical Journal* of April 17th my colleague, Mr. McDonagh, writes: "I am firmly of the opinion, from the several very toxic effects I have seen follow the use of the new products, that the successful manufacture has not been solved, and that the medical profession would be well advised to await the reports of clinicians before using the products, even if they have been passed by scientific workers and submitted to the strictest laboratory controls."

The report alluded to goes on to state: "The committee are confident that as far as the strictest laboratory controls can ensure it the profession and the public are now receiving from English and French sources compounds fully up to the standard of the best German samples previously sold." The confidence of this committee is not shared by Mr. McDonagh or by myself, both of whom have been employing these so-called "German samples" somewhat extensively for the past five years.

Whilst fully recognising the praiseworthy efforts of Messrs. Burroughs Wellcome and Co. to render this country independent of the German product, I do not consider that their efforts so far have been crowned with complete success, though I trust that in course of time they will succeed in manufacturing a substance as free from toxic effects as the preparation elaborated by Ehrlich after years of strenuous labour and after repeated disappointments.

It is within my knowledge that application has recently been made by a well-known firm to import salvarsan and neosalvarsan through a neutral country, but this application has been bluntly refused by the Board of Trade on the ground that the French firm of Poulenc Frères and the English firm Burroughs Wellcome and Co. will shortly be in a position to supply all reasonable requirements for the treatment of syphilis in this country by their salvarsan substitutes. My experience, however, precludes me from recommending the use of these substitutes, and in the absence of the original, I anticipate shortly being compelled to revert to the treatment of syphilis by mercury.

I am, Sir, yours faithfully,
J. ERNEST LANE,
Surgeon to the London Lock Hospital.
Queen Anne-street, Cavendish-square, W., April 23rd, 1915.

To the Editor of THE LANCET.

SIR,—Mr. Ernest Lane, in your issue of April 3rd, raises two questions of much importance at the present juncture. The first refers to the comparative value of the substitutes for salvarsan and neosalvarsan now on the English market, and the second to the need for preventive measures against the "inevitable increase in venereal disease at the termination of the war."

The illuminating article on "The Manufacture of Salvarsan Products in England and France," which you published on April 10th, will doubtless allay much of the feeling of distrust of the new brands which Mr. Lane's letter is sure to have excited, but I would be glad if you will allow me, with all respect, to criticise Mr. Lane's conclusions and to advance my own more favourable findings.

Mr. Lane states that while he found the results from the use of the substitutes "fairly satisfactory" their "toxic effect is much more intense," and he sounds a note of warning as to their employment. Both of the cases which Mr. Lane cites in support of the intense toxicity theory are capable of a somewhat different construction. Thus in Case 1 a course of intramuscular injections of mercury had to be interrupted owing to the onset of symptoms of mercurialism, and the dermatitis, although it followed an intravenous injection of novarsenobenzol (Billon) administered three weeks after the last mercurial injection, may have been partly or entirely a mercurial dermatitis. I have had under my care three cases of intense general dermatitis due to idiosyncrasy to mercury. Apart from this possibility, the evidence already provided of the patient's tendency to drug intolerance would indicate the need for caution and would suggest a small initial dose.

In Case 2 a second injection of kharsivan was given eight days after the first injection. For either salvarsan or kharsivan this is too short an interval if full doses are employed. Mr. Lane, unfortunately, omits to mention the dosage.

In criticising kharsivan we must not forget that it is comparable only to salvarsan and not to neosalvarsan. Both kharsivan and salvarsan are more toxic and at the same time more efficacious than neosalvarsan. The experience of my assistants and myself with kharsivan, which now covers 180 injections, leads me to conclude that its immediate and remote effects differ in no way from salvarsan. We have found that it is subject to exactly the same limitations and risks, but that it is equally beneficial in promoting the healing of syphilitic lesions. We have not been without our troubles in this series of cases, but we have no reason to blame the drug but only our methods. Two patients were seriously ill. Both of these were pregnant women who received the excessive dose of 0·6 grm. Personally I never use 0·6 grm. either of salvarsan or kharsivan. To do so in pregnant women is to invite complications. Nevertheless, in 43 out of the 180 kharsivan injections doses of 0·6 grm. were used. All of these 43 injections were given to women, and it was only amongst them that any troublesome reactions were experienced. In no case was dermatitis encountered, but more or less gastro-intestinal irritation was evident in 24 cases. Complaint only of headache was made in 4, of feeling sick in 3; vomiting was present in 19 and diarrhœa in 6. A temperature of 100° F. or over was found in 6 instances. There is here, I think, sufficient evidence to warrant the conclusion that a dose of 0·6 grm. is inadvisable, and those of us who have been using this quantity have at last been induced to abandon it. Thrombosis we have not met with since the early days of salvarsan treatment, but when kharsivan is allowed to infiltrate the tissues a cellulitis, as in the case of salvarsan, is to be expected.

That salvarsan is not less toxic than kharsivan in similar dosage is proved by our records, but space will not permit any elaboration on this point. Neosalvarsan in corresponding dosage is much less prone to excite irritation, but how neokharsivan will compare with neosalvarsan I am as yet unable to say, having used only 12 tubes of this preparation. I would like to advise, however, that the instructions accompanying the vial should be carefully read and rigidly adhered to.

With regard to Mr. Lane's plea for preventive measures calculated to control the spread of venereal diseases at the termination of the war, it is to be hoped that the Army Medical Department will endeavour, for the sake of military efficiency as well as for the public well-being, to supply effective treatment for their venereal cases.

I am, Sir, yours faithfully,
Glasgow. DAVID WATSON, M.B., C.M. Glasg.

THE MENTAL TREATMENT BILL.

To the Editor of THE LANCET.

SIR,—Now that a Bill is being promoted to make it possible for us to treat without certification soldiers and sailors suffering from serious mental disorder due to shock, this is surely an opportunity for extending similar benefits to civilians in special instances. There are many cases of mental disease in which recovery occurs comparatively quickly under systematic residential treatment, and this possibility is evidently admitted by the authorities, the whole point of the new Bill being the avoidance of the stigma of certification. Yet many persons have to be certified for conditions likely to recover within a few months because the law at present does not permit of their being taken into nursing homes or doctors' houses otherwise.

Is there any sound reason why it should not be made possible to treat such cases without certification for a period of six months, provided that certain safeguards are erected? And for this it should be sufficient for the Government to appoint several experienced alienists as special consultants for this purpose, giving them power to issue a permissory certificate to any medical man who has the care of an individual bordering on insanity, yet in whose case there is a reasonable possibility that recovery may occur soon with residential treatment. Such a certificate would be one concerning treatment only, and not affecting the status of the patient as a person of sound mind. Obviously certain conditions should be excluded from the operations of such a Bill under any circumstances, particularly general paralysis, cases of advanced dementia, and all cases exhibiting evident homicidal or suicidal tendencies.

I am, Sir, yours faithfully,
EDWIN L. ASH, M.D. Lond.
Harley-street, W., April 26th, 1915.

THE SCOTOMA OF MIGRAINE.

To the Editor of THE LANCET.

SIR,—With regard to Dr. F. W. Edridge-Green's article on the above subject in your issue of April 24th, though I do not quite follow all his arguments, nor can I produce in myself the phenomena he describes which can be noticed on awaking in the morning and looking at a white ceiling, I feel certain that he is right in attributing the scotoma to disturbance "of the circulation of the eye." I think this is shown very clearly by the following case.

A student of Guy's Hospital some 20 years ago had ocular migraine, which took the form of complete blindness of one eye, and came on very rapidly. I had the opportunity on several occasions of examining the eye when the attack was on. As far as I remember the pupil was always dilated; the ophthalmoscopic appearances were most marked and always the same. The eye could not see the light from the ophthalmoscope mirror. The retinal veins were so engorged that they looked almost bursting; the arteries—perhaps only by contrast—were thin.

On every occasion I watched the eye whilst the attack lasted, and was always able to say "You are beginning to see again," which meant that the veins were beginning to empty and gaining their natural size, which they succeeded in doing in the course of a few minutes, with complete return of sight. When this gentleman left the hospital he went into practice in a healthy seaside town, where he never had another attack. As far as I remember, but am not certain about it, he suffered from some form of heart trouble.

One of my colleagues at Guy's, long since dead, suffered in exactly the same way. He had conical cornea in one eye, and that eye was very little use to him. His first attack of migraine came on when he was in the street, fortunately not far from home. He went almost suddenly blind in his good eye and had to get someone to take him home. He was naturally very much alarmed, and it was at the beginning of his career. Whilst he was telling his wife that he feared all was over with him his sight began to return and was soon entirely restored. He consulted me about it and I told him it was migraine, and I thought due to something wrong with circulation, that he knew the worst of it and need not trouble himself about it. He had other attacks, but I never had an opportunity of examining his eye during one; at other times the eye was normal except for a low degree of myopic astigmatism. He had cardiac trouble of which he eventually died. I do not know the nature of it.

I am, Sir, yours faithfully,

Brook-street, W., April 25th, 1915. CHARLES HIGGENS.

OUR LIMBLESS SAILORS AND SOLDIERS.

To the Editor of THE LANCET.

SIR,—A great number of sailors and soldiers serving at the war have already been disabled by loss of limbs, and there will be many more before the war is ended. These men are now being discharged from hospitals and returning to their homes or friends with their wounds recently healed, and without adequate arrangements being made for their future care, comfort, or prospects. The country owes it to these gallant men that proper provision should be made for them, that they should be cared for until they have fully recovered their strength and nerve and learned how to use their new limbs, so as to become capable of taking up employment again in the form best suited to each. This cannot be done in existing hospitals.

A committee has been formed recently with the gracious approval of Her Majesty the Queen, and with the sanction of the Directors-General of the Navy and Army Medical Services, and steps will be taken immediately to establish one or more convalescent auxiliary hospitals (including an officers' branch) where these poor fellows may be concentrated and where they can get fitted and accustomed to their artificial limbs under the best conditions, with the generous advice of several eminent orthopædic surgeons. Application is being made to the Prince of Wales's Fund for a grant. We feel sure that an ever-generous public will also readily respond to our appeal. All communications and donations should be addressed to C. H. Kenderdine, St. Stephen's House, Westminster, S.W. (marked "Auxiliary Hospital").—Yours obediently,

KATHLEEN FALMOUTH,
April 29th, 1915. M. E. GWYNNE HOLFORD.

Obituary.

SIR THOMAS SMITH CLOUSTON, KT., M.D. EDIN., LL.D. EDIN. & ABERD., F.R.C.P. EDIN.,

CONSULTING PHYSICIAN, FORMERLY MEDICAL SUPERINTENDENT, TO THE ROYAL ASYLUM, MORNINGSIDE, EDINBURGH.

THE death of Sir Thomas Smith Clouston, which took place suddenly at his residence in Edinburgh on April 19th in his seventy-fourth year, has deprived the profession of one of its leading alienists. For nearly half a century he devoted himself entirely to the study of mental diseases. Born in Orkney, where his father lived, he received his early education at the West End Academy, Aberdeen, and afterwards entered the University of Edinburgh, where he had a brilliant career as a student. He qualified in 1860 as L.R.C.P. Edin. (of which College he became a Fellow in 1873), and in the following year graduated M.D. at the University, where he was the thesis gold medallist, and this, together with the winning of the Fothergill gold medal in 1870, foreshadowed the distinguished future before him. It is noteworthy that two of his fellow graduates were James Bell Pettigrew, the eminent anatomist, and John Anderson, the naturalist.

Immediately after qualifying he was appointed assistant physician under Dr. Skae at the Morningside Asylum, his two colleagues being the late Sir John Sibbold and Dr. David Yellowlees. This position he held for three years, and in 1863 was appointed superintendent of the Cumberland and Westmorland Asylum at Carlisle. He held this post for ten years, made his mark in it both as observer and administrator, and left to accept the position of physician-superintendent to the Royal Asylum, Edinburgh, where for 35 years he laboured assiduously to render the asylum a model institution for the treatment of mental diseases and a training school for alienist superintendents of other institutions throughout the world. Almost immediately after his appointment he set to work to renovate and reconstruct the institution, and the success of his labours was seen in the opening of Craig House. Some idea of the magnitude of the work of reconstruction may be realised by the fact that during the 35 years of his office the sum of £180,000 had been expended by the directors of the institution which has achieved great financial prosperity during that period.

The lectures on lunacy and cognate subjects which he delivered to the students at the Royal Edinburgh Asylum were marked by a clearness of thought and lucidity of expression which at once placed him in the forefront of teachers in mental diseases, and in 1879, six years after his appointment, he became the first lecturer in mental diseases in the University of Edinburgh. Four years later—namely, in 1883—the first edition of his lectures was published under the title of "Clinical Lectures on Mental Diseases," and the book, which has gone through six editions (the last was published in 1904) has done more perhaps than any other work on the treatment of mental diseases in spreading throughout the world enlightened methods of treatment and wise conceptions of the nature of mental aberration. Among his other notable works are the "Neuroses of Development," published in 1891, the "Hygiene of the Mind," which has seen five editions, and "Unsoundness of Mind, which was published some three years ago.

He was the editor of the *Journal of Mental Science.*

The proper scope and direction of education and the mischief and its prevention due to alcoholism, being closely associated with the subject of which he was so distinguished an exponent, were naturally among the many sociological questions with which he interested himself. His lectures on matters affecting the morality and mental health of the country were always eagerly attended and were practical in their results. He took a prominent part in the establishment of a council of public morals in Scotland. In the question of eugenics and marriage he was also much interested, his little book "Before I Wed" containing sound and practical advice of a much needed character. In 1910 he gave evidence on behalf of the British Medical Association before the Royal Commission on Divorce and Matrimonial Causes.

Of the many honours which were bestowed upon Sir Thomas Clouston in the course of his life he valued none more highly than that of the freedom of Kirkwall, the capital town of his native Orkney, which he received in 1908. He was an ex-President of the Medico-Psychological Association and of the Edinburgh Medico-Chirurgical Society, and was President of the Royal College of Physicians of Edinburgh in 1902 and 1903. The University of Aberdeen conferred upon him in 1907 the honorary distinction of LL.D., and in 1911, when the King and Queen visited Edinburgh, he was knighted. In the same year the University of Edinburgh conferred upon him its honorary Doctorate of Laws. During the annual meeting of the British Medical Association at Edinburgh in 1875 Dr. Clouston was Vice-President of the Section of Psychology and President of the same section at the meetings held at Brighton in 1886 and at Edinburgh in 1898.

Dr. Clouston married Harriet Segur, the daughter of William Storer, of New Haven, Connecticut, U.S.A., who survives him, with two sons and one daughter, the latter being the wife of Dr. David Wallace, C.M.G., surgeon to the Edinburgh Royal Infirmary. One of his sons is the well-known humorous writer, Mr. J. Storer Clouston.

EDWIN THOMAS MOSSE TUNNICLIFFE, M.R.C.S., L.S.A.

THE death of Mr. Edwin Thomas Mosse Tunnicliffe, of Biana, North Finchley, occurred suddenly on April 15th last, while playing golf. Death was due to a form of morbus cordis, Adams-Stokes disease, of which he had had several previous attacks.

E. T. M. Tunnicliffe was born in 1860, and was the son of Frederick Warner Tunnicliffe, of Biana, Eccleshall, Staffs. He was educated at private schools, and, making up his mind to enter the medical profession rather later than the average student, joined St. Bartholomew's Hospital in 1883. He qualified L.S.A. in 1887, and M.R.C.S. in 1888, and almost immediately bought a small share in an old-established practice at North Finchley and Whetstone. The practice increased rapidly and in 1902 the firm dissolved partnership. For four years Tunnicliffe worked a very large practice single-handed and the early symptoms of the breakdown which followed occurred during this strenuous time. In 1906 he was fortunate in obtaining a partner who much relieved the strain of work, and at the time the end came, Tunnicliffe was thinking of slowing down and gradually retiring from practice, a sadly common position.

From a small beginning Tunnicliffe built up one of the largest practices in his district. All who met him in consultation, and they were many, recognised at once that they were dealing with a man well trained in the principles of medicine and surgery, scrupulous in his regard for medical ethics, and thoroughly capable of estimating the relative value of clinical fact. The respect in which he was held by his patients was testified to by the number of people attending his funeral and by the very many tokens of condolence sent. He leaves a widow, a son who is just completing his training at Sandhurst, and a daughter, to whom in their bereavement the sympathy of the medical profession will go out.

THE LATE DR. J. H. BENDLE.—We published last week a short note of the death of Dr. J. H. Bendle, the county oculist for Somerset. We have since received from Dr. W. G. Parker the following appreciation of the late Dr. Bendle's work:—"Dr. Bendle was my colleague in the school medical service in Somerset for over six years. His death is a great personal loss to his colleagues, to whom he was always a true friend and loyal comrade. Perhaps one of his most outstanding characteristics was his loyalty to his friends, of whom he had many. He was a good companion, could tell a good story and tell it well, and an evening spent with him was never dull. A supremely conscientious worker, who devoted much care to detail, he was also a sound and capable practitioner with a wide knowledge, which he brought to bear on his work. In his work as school oculist, each individual case received careful thought, as well as a thorough examination, and he was never satisfied with any result but the best possible. He remembered and followed up his cases for years, taking a great interest in them and keenly watching their progress. He never spared himself, and spent at his work many hours which should have been free for rest and recreation. Both as an official and as a man he set and lived up to a very high standard. His death is a great loss to the school medical service, and his place will be a difficult one to fill satisfactorily."

DEATH OF DR. JOSEPH HARWOOD WILSON, OF STANDISH, LANCS.—Dr. J. H. Wilson died on April 8th, at the age of 49, after only a few days' illness. He received his early education at Wigan Grammar School, afterwards proceeding to Eastbourne College, Owens College, and Durham University, where he graduated in 1887. He first entered upon practice at Hull, and went to Standish about 23 years ago. Here he was appointed medical officer of health to the urban district council and to the Standish district of the Wigan Union. He also became surgeon to the Lancashire and Cheshire Miners' Permanent Relief Society and surgeon to the Standish Branch of the British Red Cross Society, being in charge of the Woodlands No. 3 Hospital. He leaves a widow.

THE LATE MR. FRANCIS JOHN AUGUSTUS BALDWIN.—An inquest was held at Padstow, Cornwall, on April 22nd on the body of Mr. F. J. A. Baldwin, which was recovered from the sea the day previous. Mr. Baldwin was a passenger on the *Falaba*, which was torpedoed by a German submarine on March 28th in St. George's Channel. The jury returned a verdict of "Found drowned," and expressed indignation at the inhuman conduct of the crew of the submarine in sinking the *Falaba*. Mr. Baldwin, who was 55 years of age, was in the Colonial Medical Service at Nigeria, West Africa. He was also a justice of the peace and deputy coroner.

THE LATE BENJAMIN D. C. BELL, L.R.C.P., L.R.C.S. Edin., J.P.—The death of Mr. Benjamin Bell took place at his residence in Kirkwall, Orkney, on April 7th, at the age of 55. He was a native of Shetland, and was educated in Edinburgh, where he qualified L.R.C.P., L.R.C.S. in 1884, in which year he commenced practice in Orkney. He was medical officer of the Borough of Kirkwall, and held a number of other public appointments. He leaves a widow, a daughter of Sir Alexander Christison, Bart.

The War.

THE CASUALTY LIST.

AMONG the names of officers appearing in the casualty lists published since our last issue are the following:—

Killed: Second Lieutenant Hugh Bertrand Neely, of the Suffolk Regiment, a former student of Guy's Hospital and an L.D.S.

Wounded: Major H. A. J. Gidney, I.M.S., and Captain E. Percival, R.A.M.C.

THE HONOURS LIST.

Temporary Lieutenant James Robertson Campbell Greenlees, R.A.M.C., has been appointed D.S.O. for his great gallantry and devotion to duty at Neuve Chapelle from March 10th to 14th, 1915, in attending on the wounded under very heavy fire. Lieutenant Greenlees has twice before been brought to notice for similar conduct.—Lieutenant J. G. Priestley, R.A.M.C., has been awarded the Military Cross for gallantry and devotion to duty at Neuve Chapelle on March 13th, 1915, when he continued attending to the wounded with great bravery, although himself badly wounded.

The Military Cross has been awarded to Lieutenant A. C. Hincks, R.A.M.C., for conspicuous gallantry and devotion to duty at Neuve Chapelle from March 11th to 14th, in collecting the wounded whilst under heavy fire. On the night of March 13th and 14th, whilst he was attending on a wounded man, a shell struck the ambulance wagon, killing the man and rendering Lieutenant Hincks unconscious. On recovering he at once proceeded to collect the wounded under fire, and continued doing so throughout the night.

THE WORK OF THE ROYAL ARMY MEDICAL CORPS AT THE FRONT.

Mr. Tennant, the Under Secretary for War, made a statement this week in the House of Commons with regard to the work of the Royal Army Medical Corps at the front which must prove extremely gratifying not only to that corps and to the authorities of the Army Medical Service but also to the whole medical profession. He described the health of the British troops as singularly good throughout, taking into consideration all the circumstances of the existing war, and he based his opinion upon a very clear appreciation of what has really happened. His praise was well informed; the early critics of the Royal Army Medical Corps were not. Our army has been attacked, as it was bound to be, by different epidemic diseases at different places, but the measures of control have been prompt and thorough, with the result that the mischief threatened by measles and enteric fever has been promptly circumscribed. There is not a single case of dysentery amongst our troops, said Mr. Tennant, and we agree with him that that fact is a remarkable one. Such freedom of our army from disease constitutes the most speaking tribute to the work of the Royal Army Medical Corps, but preventive medicine and sanitation are not the only fields in which their work has been extremely fine. The arrangements for the care of the wounded, for bringing them from the trenches to the clearing stations, from those stations to base hospitals, and, finally, to this country, have alike been marked by efficiency, promptitude, and humanity. We know how well deserved are Mr. Tennant's eulogies of the Royal Army Medical Corps, and we hope that his words will be widely read. Perhaps they will meet the eyes of some of those who, failing to realise the conditions of war at all, found the medical care of the wounded at the battle of Mons, for example, inadequate. The public should know more now of the way in which war is waged than it did in September. In September the public was inclined to be critical of the Royal Army Medical Corps, and we received communications stating that our wounded were not receiving the treatment that they had the right to expect. This was in the terrible days which marked the arrival of our Expeditionary Forces at the front. They were immediately compelled to retire in the face of overwhelming numbers and were subjected on many occasions to heavy slaughter. It is obvious that the battlefields upon which our wounded lay were immediately occupied by the enemy, that the places of retirement selected for dressing stations could no longer be used, and that situations designed for clearing hospitals came early within the range of attack. The recognised routine for collecting the wounded, for sorting them, and for evacuating them was thrown out of gear. Every endeavour was made to collect as many wounded as possible, and despite the personal risks incurred in the task it was attempted to give first aid to those collected and where possible to arrange for their transport to more permanent shelter. Ever since those terrible days when the medico-military service, sharing the fortunes of the army which it accompanied, had for a time to give way to superior force the care of our wounded in the field has been admirably organised and the system of the work of the Royal Army Medical Corps has been the special admiration of our Allies. We hope some of the early critics of the corps will note Mr. Tennant's words.

ASPHYXIATING GASES IN WARFARE.

There has been considerable speculation as to what were the asphyxiating gases employed by the Germans in recent engagements. The point is of some interest since the method for a time gave an undoubted advantage to the ruthless enemy. From the accounts of sufferers and medical observers it seemed clear from the outset that one of three gases had been used—chlorine, sulphur dioxide, and nitrogen tetroxide—and an official report from Mr. J. S. Haldane, F.R.S., our greatest scientific expert on the physiology of respiration in poisonous conditions, now pronounces in favour of chlorine or bromine. These are all heavy, irritating gases and cheaply produced, except bromine, whose employment can only have been mentioned as a possibility. All are coloured gases, except sulphur dioxide, which, however, may assume a yellow colour if made from sulphur sprinkled on burning wood. It would seem doubtful, however, if fire was used in the production of the gas, inasmuch as the heat of the combustion would cause the vapours to ascend rapidly at the point of production, when they would be largely diluted with air. This seemed from the first to rule out sulphur dioxide; moreover, if this gas had been used the description of the fumes as "sulphurous" would surely have been reported. No such familiar word was used. The employment of nitrogen tetroxide for the purpose was improbable, since it would be employing a valuable constituent of explosives. Nor could the suggestion that the gas was carbon monoxide be accepted, since this gas is, of course, colourless, while it is slightly lighter than air. To the chemist the evidence was at once considerably in favour of chlorine having been used in some form or other. This gas is very cheap, and is easily liquefied and preserved in metal cylinders. It is heavy and is yellowish or yellowish-green in colour. It may readily be generated from bleaching powder used in the portable form of cubes. Chlorine is a strongly asphyxiating gas, which takes a long time to mix with air, being two and a half times as heavy.

It is fortunate that the methods of prevention are similar in each case. All these gases are soluble in water and are of an acid nature. A wet cloth (preferably with some carbonate of soda) should be placed over the mouth, and breathing should take place through the mouth, returning expired air through the nose. This procedure will practically defeat the diabolical design, which to some extent loses its terrors with its mystery. The gas can only be used comparatively locally.

SCOTTISH MILITARY HOSPITAL AT BANGOUR.—Negotiations have been completed for the taking over of Bangour Village by the War Office for the purpose of a great military hospital. It is at Bangour that the Edinburgh District Asylum is situated, an institution that comes next to Woodilee and Hartwood in point of size among Scottish asylums, and is one of the most up-to-date mental treatment centres in the United Kingdom. The transfer of the ordinary inmates to other asylums all over Scotland has already commenced, and it is expected that the village will be ready for occupation as a hospital for sick and wounded soldiers in six weeks' time. While the conversion of other public institutions into military hospitals is not uncommon, as, for example, Craigleith Hospital, this is the first instance in Scotland in which an asylum has been so utilised. The step which has now been taken, however, is merely in development of a scheme which has been in progress in England for several months. In regard to Bangour, the first step taken was when the military authorities approached the General Board of Control for Scotland at the end of March "with the object of obtaining the use of an asylum in the vicinity of Edinburgh capable of providing accommodation for upwards of 1000 sick and wounded soldiers." On considering the matter the Board of Control came to the conclusion that the Edinburgh District Asylum was the only institution that fulfilled the War Office requirements, and they accordingly advanced the proposition to the District Board of Control that the asylum be handed over. Simultaneously, the Scottish Board of Control addressed a letter to the other district boards throughout Scotland, inviting their coöperation in the work of transferring the patients which must follow the conversion of such an institution into a military hospital. The response of the Edinburgh District Board was one of prompt and hearty concurrence, and the ready way in which the other local authorities fell in with the general body's appeal disposed of any misgivings as to the alternative housing of the patients. From all parts of the country offers have been made to receive a certain number of patients, which in the aggregate more than covers the total number (890) at present accommodated at Bangour. At the Royal Asylum at Morningside 50 cases of sick people have already been received, whose removal further afield might have been undesirable. Other centres to which patients will be transferred are Melrose, Rosslynlee, Haddington, Fife, Larbert, Hartwood, Hawkhead, Ayr, Dumfries, Lochgilphead, Perth, Murthly, Montrose, Dundee, Aberdeen, Elgin, Banff, and Inverness. The Royal Asylum, Morningside, will act as receiving hospital for all the cases of insanity occurring in Edinburgh during the military occupation of Bangour. Although the accommodation for insane persons at Bangour is less than 1000 beds, investigation has shown that it will be possible comfortably to acccommodate 1350 sick and wounded, for the dining rooms and sitting rooms necessary in the case of insane patients may, in the case of wounded men, be converted into wards. The military authorities after inspection have declared the hospital admirably suited to the object in view.

The War Office will take over the institution as a "going concern." The only exception will be in regard to the farm, which will continue under the control of the District Board, a certain number of patients being retained for its working. The produce will, as usual, go to supply the institution. Few structural alterations will be necessary, though naturally considerable extra equipment will be required, but the provision of this will be made by the War Office or by the District Board on their behalf. The present hospital has an operating room, a laboratory for bacteriological work, and an electrical room (with X ray apparatus); but a second operating theatre will be necessary. The full staff will be retained at present, but a staff of visiting physicians and surgeons will also be appointed, and the resident and nursing staff will be increased. The present staff numbers 200, and it may be noted that close on 50, including two doctors and several nurses, are serving at home and abroad. Bangour has greatly developed in every way since its establishment. When the first patient was received on June 1st, 1904, there was accommodation for only 200; now almost five times that number are receiving treatment. Bangour is situated in the parish of Uphall, in the county of Linlithgow, and the estate in the hands of the District Board comprises 960 acres. The asylum is built on the village plan, and consists of a medical section and an industrial section. In the medical section are accommodated recent and acute cases, and those requiring special supervision or hospital treatment. This section comprises the admission ward, 120 beds; four villas, with 150 beds between them; a hospital, with 150 beds; and a sanatorium, with 20 beds. In the medical section there is also a nurses' home, with accommodation for 80 nurses. Among the houses in the industrial section there is accommodation for 460 patients—200 women and 260 men. There are also buildings common to both sections of the institution, such as a recreation hall, having a seating capacity for over 700 persons. The bakery, kitchen, stores, and laundry are capable of providing for a population of at least 1500. Bread for the entire village is baked at this bakery, and another source of food-supply is the farm, the dairy and vegetable produce of which is considerable. The buildings are situated about 500 feet above sea-level on a gentle southern slope. The air is bracing, the estate well wooded. In the opinion of the army authorities it admirably meets the soldier's requirements—rest and quietness. A railway station in the grounds constitutes an important additional convenience.

Dr. John Keay, who will continue to act as medical superintendent, was appointed to the institution on its establishment.

VACANCIES FOR MEDICAL OFFICERS.—We are informed that there are vacancies for two or three more medical officers in the 3/3rd H. C. Field Ambulance. As this unit has only just been formed, qualified medical men will have the opportunity of getting a full insight into their military duties during the training of the men. As so many medical men fear that their ignorance of drill and general army routine may handicap their efficiency, this chance of gradual training may offer special inducement. Applications should be addressed to Major E. A. Houchin, R.A.M.C., Officer Commanding, 62, Claremont-road, Surbiton, Surrey.

AID FOR BLINDED SAILORS AND SOLDIERS.—St. Dunstan's Blinded Soldiers' and Sailors' Hostel, Regent's Park, N.W., organised by Mr. C. Arthur Pearson, chairman of the Blinded Sailors' and Soldiers' Care Committee, is conducted with the concurrence and support of the War Office, the National Relief Fund, the Red Cross Society, and the Order of St. John, and the National Institute for the Blind. Everything suggested by the most careful thought of men and women best qualified to advise as to the needs of the blind is to be found there, for the Blinded Sailors' and Soldiers' Care Committee has not depended upon its own unaided efforts, but has called to its assistance experts in the treatment of the blind from all parts of the kingdom, and it is consequently in a position to offer the blinded sailor and soldier advantages which are of the highest order, including the provision of a seaside home situated at Brighton. Almost without exception those responsible for institutions for the blind are working in coöperation with it, and are helping blinded sailors and soldiers with whom they come in contact to participate in the advantages thus open to them. Every inmate of the institution is taught some means of gaining a livelihood and is instructed in the Braille system of reading and writing by blind instructors, a fact which imparts a most useful initial confidence. The house, which was lent by Mr. Otto Kahn, stands in 15 acres of ground and thus enables poultry-farming and market-gardening—the latter under the care of Captain Pierson-Webber, himself a blind expert in the craft—to be added to boot-making, mat-making, basket-making, carpentering, massage, and other occupations that can be pursued by the blind.

At a meeting of the board of directors of the Royal Blind Asylum and School, Edinburgh, held on April 26th, it was agreed, on the recommendation of the Blinded Sailors' and Soldiers' Care Committee, to establish in Edinburgh a training centre where blind Scottish sailors and soldiers shall be taught "to be blind," trained to read and write in Braille, and in such handicrafts as may be found suitable. If necessary a residence or hostel will be established for the temporary accommodation of those receiving such training. The Scottish Branch of the Red Cross Society, the various Scottish institutions and societies for the blind, and the Naval and Military authorities will be invited to coöperate in the work by reporting to the institution all blind sailors and soldiers coming under their notice; and application will be made to the National Relief (Prince of Wales') Fund and the Scottish Red Cross Society for grants to meet the expenses incurred. An appeal will also be made to the public for subscriptions.

THE KING GEORGE HOSPITAL.—The large building near Waterloo Station has made steady progress towards completion, and is now practically ready for occupation. The equipment and provision of the building for 1650 patients has been, of course, a very costly affair, and especially so as the price of a good deal of the material has risen considerably of late.

The last call is for five microscopes for use in the wards, and the committee venture to ask if any members of our profession would be willing to lend them (as people have been kind enough to lend field-glasses and periscopes to the troops at the front). The microscopes should have a half and a quarter inch objective. Sir Frederick Treves and Mr. Edmund Owen would be glad to hear of anyone who is ready to come forward with an offer, and they would do their best towards seeing that the microscopes are duly returned to their owners when the hospital is closed. The office of the joint committee is at 83, Pall Mall, S.W., to which correspondence on the subject may be sent.

SUSPENSION OF INDIAN MEDICAL SERVICE EXAMINATION.—It has been officially announced that the open competitive examination for appointments in the Indian Medical Service will be discontinued for the duration of the war after the July examination. Instead, the Secretary of State for India will nominate to such appointments as may be necessary during the interim, and on the cessation of the war will make necessary appointments from qualified persons, either European or Indian, who have held temporary commissions during the war in the Indian Medical Service or Royal Army Medical Corps, or who have served with British or Indian Expeditionary forces, hospitals, or hospital ships. Due announcement will be made when the ordinary examinations are to be resumed.

FROM A HOSPITAL IN THE SAVOY.—An English correspondent in charge of a hospital behind the southern lines of the French army has sent us a description of hospital life which shows clearly that our allies in their recent successful advances have cheerfully paid the price of war. While the French casualties have been less than those of the Germans, they have none the less been large, and a number of very serious injuries occur daily. "The removal of damaged tissues, splinters of bone, and wayward missiles gets monotonous in the long run," writes our correspondent, "and we welcome anything for a change. I have a case of cerebrospinal meningitis in a farm lad 15 miles away from hospital. I did lumbar puncture and centrifugalised the cerebro-spinal fluid, and made a preparation, stained it, and obtained the diplococcus, and sent a message to the Prefecture at Chambéry for a supply of serum, which duly arrived. (My device for a centrifugator is to tie the test-tube with sticking plaster to a spoke of my motor cycle and set the engine going. In five minutes 'ca y est.') I rather expected, given the proximity of so many soldiers, that the authorities would have communicated with me further, but there is a gratifying confidence that all steps with regard to the spread of disease will be taken by us upon our own initiative. I am engaged in a very busy practice extending 20 miles round. It is appalling what a quantity of phthisis there is about. The well-to-do sturdy peasant farmers' houses are filthy; the inside walls are rough uncoated stone, with millions of little ridges and added shelves for dust collection, and totally unwashed floors. When I remonstrate I am told, 'The fact is, there is no one to attend to such things.' 'But,' I say, 'you might smear mud over the walls and make them smooth with a layer of limewash as the Arabs do, and you might scrub your floors now and then, for there are plenty of women.' 'Oh,' they say, 'everybody works on the land, and when they have done their day's work no one has the energy to turn-to indoors. So there you are!" Our correspondent winds up by extolling the thrift and good sense of the French peasants in making palatable salads out of dandelions and nettles.

WOUNDED ALLIES RELIEF COMMITTEE.—HELP FOR MONTENEGRO.—The Wounded Allies Relief Committee has decided, in consequence of the spread of typhus and typhoid fever in Montenegro, to despatch to Montenegro Dr. Isabel Ormiston, an Australian lady, and a graduate of Sydney University and Chief Medical Inspector of Schools to the Government of Tasmania. Dr. Ormiston was in charge of the Kursaal Hospital at Ostend, until she and the English Voluntary Aid Detachment which assisted her were ordered by the Germans into Holland. Since Christmas she has been working at the Queen of the Belgians' Hospital at La Panne. When Dr. Ormiston has reported to the committee on a suitable base, means of transport, and the most desirable type of unit, her requirements will be despatched with the minimum of delay. All contributions towards the unit, which will be provided with an ample supply of disinfectants, disinfectors, and destructors, will be gratefully received by the honorary treasurer, Mr. T. O. Roberts (manager), London County and Westminster Bank, 217, Strand, W.C.

THE NATIONAL COMMITTEE FOR RELIEF IN BELGIUM.—This committee has issued during the week a powerful appeal for assistance in money to meet the terrible emergency in Belgium, which is stated to be no less than the slow starvation of much of the population. The appeal is signed by the Archbishop of Canterbury, Cardinal Vaughan, the Lord Mayor of London, the Duke of Norfolk, Lord Rosebery, and other influential persons, and the treasurer is Mr. A. Shirley Benn, M.P.

GRATUITOUS TREATMENT OF OFFICERS AT AIX-LES-BAINS.—Arrangements have been made for carrying on the treatment at the bathing establishment, which is State property, as usual. It has been intimated to the director, Dr. Durand Desmond, that his proposal to accord gratuitous treatment to sick and wounded officers of the Allied Armies has been officially approved. This is a valuable offer in view of the large number who have contracted rheumatism in the trenches, or have been left with damaged or stiff joints as the result of wounds. A certain number of the principal hotels have been reopened in order to provide accommodation for visitors, and the hotel proprietors' syndicate announce a special tariff varying from 5 to 10 francs a day, inclusive, for convalescent officers. The Casino will open shortly, and provision will be made for light musical entertainments. The train service between Paris and Aix is as rapid and as comfortable as heretofore.

SURGICAL DRESSINGS FOR THE ALLIES.—The Kensington War Hospital Supply Depôt, situated at 11–12, Kensington-square, has over 600 workers coöperating with the Kensington division of the Red Cross Society in the production of surgical dressings and comforts for the soldiers. These workers, besides their labour, provide between them sufficient funds to meet the weekly expenses of the depôt. But as their present premises do not allow them to keep pace with the demands, they appeal for gifts of old linen, dressing-gowns, shirts, socks, slippers, and rubber hot-water bottles. We are informed that, encouraged by the success that attended on the Kensington War Hospital Supply Depôt, its organiser, Miss Ethel McCaul, has opened a second depôt at 32, Queen Anne-street, Cavendish-square, under the presidency of Alderman John Fettes, J.P. The committee consists of Sir Thomas Barlow, Sir W. Watson Cheyne, Sir Rickman Godlee, and Dr. Frederick Taylor. The secretary is Mr. Frank Juler.

MEDICAL RELIEF FOR SERBIA.—Sir Thomas Lipton's yacht is announced to make a second cruise in connexion with Serbian relief, sailing on May 1st from Southampton for Salonika and returning in about two months. Dr. Elsie Inglis, who organised the Scottish Women's Hospitals in Serbia and France, herself left for Kragujevatz, in Serbia, on April 24th to visit the hospital, which has been at work there since December among the wounded and the typhus-stricken. The staff, over 50 in number, are entirely women.

WAR MAPS.—We referred in THE LANCET of August 15th, 1914, to Maps 1, 2, and 3, and in that of Sept. 5th, 1914, to Maps 4, 5, 6, and 7 of the excellent series of war maps published by Messrs. Stanford, Ltd., of Long Acre, London, W.C. There have since been published No. 8, the seat of war in Eastern Europe; No. 9, the seat of war in Turkey; No. 10, the seat of war in Armenia; No. 11, the theatre of war in Eastern Europe; and No. 12, the theatre of war in Western Asia Minor. The maps are legibly lettered.

THE LLOYD MEMORIAL (CAXTON) SEASIDE HOME, DEAL.—A dinner will be given, under the presidency of Lord Northcliffe, at the Hotel Cecil, on June 5th, in aid of this home, which, being supported by upwards of 6000 members of the printing and allied trades, has placed at the disposal of the War Office 12 beds for the use of convalescent soldiers enlisted from those trades.

Medical News.

SOCIETY OF APOTHECARIES OF LONDON.—At examinations held recently the following candidates passed in the subjects indicated:—

Surgery.—C. D. Banes (Section I.), King's College Hospital; B. A. Bull (Sections I. and II.), Oxford and St. Bartholomew's Hospital; R. Curle (Sections I. and II.), Guy's Hospital; L. Lee (Section I.), Geneva; J. G. Lewis (Section II.), Durham; H. Morrison (Section I.), St. Mary's Hospital; D. C. Ogilvie (Sections I. and II.), Middlesex Hospital; R. Quesada-Jiménez (Sections I. and II.), Guy's Hospital; W. H. Rhys-Jones (Sections I. and II.), Charing Cross Hospital; J. A. W. Robinson (Sections I. and II.), King's College Hospital; G. S. Stathers (Sections I. and II.), Cambridge and St. Bartholomew's Hospitals; and H. E. P. Yorke (Sections I. and II.), St. Bartholomew's Hospital.

Medicine.—B. A. Bull (Sections I. and II.), Oxford and St. Bartholomew's Hospital; A. Butterfield (Section I.), Durham; J. E. Cheesman (Sections I. and II.), St. Mary's Hospital; R. Curle (Sections I. and II.), Guy's Hospital; H. A. de Morgan (Sections I. and II.), Middlesex Hospital; J. B. Fairclough (Sections I. and II.), Leeds and Guy's Hospital; W. Fox (Section I.), Charing Cross Hospital; L. A. J. Graham (Sections I. and II.), Cambridge and Guy's Hospital; N. Hoffmeister (Sections I. and II.), Middlesex Hospital; L. Lee (Sections I. and II.), Geneva; (J. G. Lewis Section II.), Durham; D. C. Ogilvie (Sections I. and II.), Middlesex Hospital; J. A. W. Robinson (Section II.) and E. E. Samaraweera (Sections I. and II.), King's College Hospital; and H. E. P. Yorke (Sections I. and II.), St. Bartholomew's Hospital.

Forensic Medicine.—G. T. Baker, Middlesex Hospital; A. Butterfield, Durham; L. Lee, Geneva; J. Mitchell, Edinburgh; J. E. Rusby, Leeds; E. E. Samaraweera, King's College Hospital; and H. E. P. Yorke, St. Bartholomew's Hospital.

Midwifery.—A. Z. Absushady, St. George's Hospital; H. Archer, Bristol; J. B. Fairclough, Leeds and Guy's Hospital; W. Fox, Charing Cross Hospital; J. L. Hamilton, London Hospital; H. L. Hughes, St. George's Hospital; L. Lee, Geneva; J. E. Rusby, Leeds; and C. P. C, Sargent and H. E. P. Yorke, St. Bartholomew's Hospital.

The Diploma of the Society was granted to the following candidates entitling them to practise medicine, surgery, and midwifery:—B. A. Bull, R. Curle, L. A. J. Graham, R. Quesada-Jiménez, J. G. Lewis, D. C. Ogilvie, W. H. Rhys-Jones, J. A. W. Robinson, and H. E. P. Yorke.

THE Radcliff Prize at Oxford has been awarded to Dr. Martin William Flack, a former Radcliffe Travelling Fellow and a member of the staff of the National Health Insurance Medical Research Committee.

THE ASSURANCE MEDICAL SOCIETY.—The next ordinary meeting of this society will be held at the House of the Royal Society of Medicine, 1, Wimpole-street, London, W., on Wednesday next, May 5th, at 5.30 P.M., when Sir Thomas Oliver, M.D., F.R.C.P., will read a paper on the Rôle of Traumatism in Disease calling for Compensation. There will be a council meeting at 5 P.M. All communications should be made to the honorary secretaries, Dr. R. A. Young, 57, Harley-street, W., and Dr. Otto May, 65, Harley-street, W.

WEST LONDON MEDICO-CHIRURGICAL SOCIETY.—A reception, at which many ladies were present, was held on the evening of St. George's Day, April 23rd, at the West London Hospital and Post-Graduate College, by the President and Council to meet the members and the Belgian doctors. Dr. Jacobs, Président d'honneur de la Société de Gynécologie de Belgique, gave an interesting address in English on Belgium, Belgian Doctors, and the Germans. Colonel Sir Charles Watson, K.C.M.G., C.B., gave a historical account, illustrated by lantern slides, of the rise and progress of the Order of St. John of Jerusalem up to the present date. Colonel T. H. Hendley, C.I.E., I.M.S. (retired), lectured on War in Indian Art. In the various annexes were exhibited Belgian War Relics, by Mr. H. S. Souttar; War Relics, by Mr. Donald Armour; Skiagrams of Projectiles, by Dr. Reginald Morton; Indian War Pictures, by Colonel Hendley; and War Relics from the Cameroons, by Mr. Leonard Bidwell, R.N., son of the late well-known surgeon and Dean of the West London Post-Graduate College. An excellent programme of music was provided, including a repertoire of Montmartre songs by M. Edouard Garceau.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Mental Treatment Bill.

THE Mental Treatment Bill, which Mr. CECIL HARMSWORTH, the Under Secretary for Home Affairs, has introduced in the House of Commons, is an important measure which has been necessitated by the war. Its object, briefly stated, is "to facilitate the early treatment of mental disorder of recent origin arising from wounds, shock, and other causes." Its text has now been issued. A Memorandum attached to it gives a brief summary of the law and the changes which it is proposed to effect in it.

The Memorandum.

As the law now stands (the Memorandum states) nursing homes cannot receive for treatment patients who are suffering from nervous breakdown affecting their mental condition (Lunacy Act, 1890, section 315 (2)). Such patients can only obtain residential treatment if they are certified insane and sent to an asylum or hospital under the Lunacy Acts. This applies even if the breakdown is of a temporary character and almost certainly capable of being cured. As it is found that a sort of stigma attaches throughout life to a person who has once been certified as insane, there is great reluctance to have such cases certified, and the result is that persons suffering from temporary mental disorder do not receive the special treatment in a nursing home which is suitable to their condition and which is calculated to effect a speedy cure.

The object of the present Bill (the Memorandum proceeds to state) is to secure the proper treatment of such cases by making the law less rigid than at present. It removes the necessity for formal certification in the case of persons suffering from mental breakdown of recent origin and arising from wounds, shock, &c. In this respect it assimilates the English law to the law which has been in force in Scotland for 50 years and which has worked satisfactorily [Lunacy (Scotland) Act, 1866, section 13].

It is brought forward at the present moment in order to meet an urgent need which has arisen in the case of soldiers and sailors invalided from the front, and others whose health has broken down under the stress engendered by the war.

This Bill will enable a man who in the service of his country has suffered a nervous breakdown to accept the treatment without being certified, but only for a period not exceeding six months and under conditions which will provide security against misuse.

The Text of the Bill.

As the provisions of the Bill are important we now quote them in full.

Clause 1, power to receive persons suffering from mental disorder of recent origin arising from wounds, &c., runs as follows: (1) Notwithstanding the provisions in any other Act to the contrary, a person shall not be liable to any penalty for receiving to board or lodge or for taking charge of, whether for payment or not, any person suffering from mental disorder of recent origin arising from wounds, shock, disease, stress, exhaustion, or any other cause, if and so long as he complies with the conditions imposed by regulations made under this Act.

(2) Regulations may be made in England by the Secretary of State with the concurrence of the Lord Chancellor, and in Ireland by the Lord Chancellor of Ireland, as to (*a*) the period, not exceeding six months, for which such a person may be so received; (*b*) the institutions, homes, or houses into which such a person may be received; (*c*) the statements and notices to be furnished as respects a person so received; (*d*) the treatment of persons so received and their visitation, removal to other care, and discharge.

(3) Regulations made under this Act shall be laid before each House of Parliament as soon as may be after they are made, and if an address is presented to His Majesty by either House of Parliament within the next subsequent 21 days on which the House has sat praying that any such regulations may be annulled, His Majesty in Council may annul the regulations, and they shall be thenceforth void, but without prejudice to anything previously done thereunder before the expiration of the said period, and the regulations made under this Act shall have effect as if enacted in this Act.

Clause 2 (short title, extent, and duration) reads:—(1) This Act may be cited as the Mental Treatment Act, 1915. (2) This Act shall not extend to Scotland. (3) This Act shall continue in force during the continuance of the present war and for a period of six months thereafter and no longer, except that, as respects persons who at the end of the said period of six months are receiving treatment under this Act, it shall continue in force so long as they continue to receive such treatment.

The Position of Territorial Medical Officers.

Attention should be called to the statement made in the debate on War Office Estimates by Mr. H. BAKER, the Financial Secretary to the War Office, in regard to the position of medical officers of the Territorial Force. Reference was made in the course of the discussion to the sacrifices of these gentlemen in leaving their practices and to the less favourable conditions which were given to them as compared with those afforded to medical men who had accepted temporary commissions in the Royal Army Medical Corps. Mr. BAKER said that something should be done with regard to promotions, and the question of a gratuity, such as had been offered to medical officers specially enlisted after mobilisation on the outbreak of war, was also under consideration. He hoped that the question would shortly be decided. During the debate a high tribute to the excellence of the medical service in the war was paid by Mr. TENNANT, the Under Secretary for War.

Treatment of Prisoners of War in Germany.

Debates took place in both Houses of Parliament on Tuesday, April 27th, on the subject of the ill-treatment of British prisoners of war in Germany. That country, to use the words of Lord KITCHENER, has stooped to acts which will surely stain indelibly her military history and vie with the barbarous savagery of the Dervishes of the Soudan. "I think it is only right and fair to say," proceeded the Secretary of State for War, "that the German hospitals should be excepted from any charges of deliberate inhumanity. There have been indications of a lamentable lack of medical skill, and, in individual cases, of neglect and indifference to suffering on the part of hospital orderlies. On the other hand, there are statements from prisoners who have been released as incapacitated that their experiences in hospital had not formed any ground for special complaint."

In the House of Commons Mr. J. M. HENDERSON, who has taken a personal interest in this matter, said that his experience in regard to wounded prisoners pointed to good treatment in German hospitals. He knew of four cases of soldiers who received dangerous and difficult wounds, which had taken months to heal, but they had been healed. The greatest pains, assiduity, and care had been devoted to them by surgeons in German hospitals, and in each one of those cases it would have been a very easy thing to lose a limb. Not one had lost a limb and all were convalescent at the present moment.

The position which the debate revealed in regard to unwounded prisoners who were confined in camps in Germany was, on the contrary, very painful. The PRIME MINISTER characterised it as a horrible story and one of the blackest spots on the records even of German methods of warfare.

HOUSE OF COMMONS.

WEDNESDAY, APRIL 21ST.

Tinctures and the Spirit Duty.

Mr. BRIDGEMAN asked the Chancellor of the Exchequer whether he had reconsidered the question of giving an exemption from spirit duty to hospitals using a large quantity for tinctures in surgical work; and whether there was any reason why any such exemption could not be given to hospitals without also giving it to doctors and chemists.—Mr. LLOYD GEORGE replied: I am considering the honourable Member's suggestion.

Certification for Sickness Benefit in Ireland.

Mr. GINNELL asked the Chancellor of the Duchy what independent medical approval, if any, the Irish Insurance Commissioners had for the treatment of the sick which their different system of certification involved; and to what cause, except inability to get such approval, their failure was due in a matter of which both the sick and the medical profession complained.—Mr. ACLAND (on behalf of Mr. MONTAGU): My right honourable friend fears that he is unable to add anything to the full replies already given on this subject; but he may say that the question of revising the present arrangement is under consideration, and he will be happy to inform the honourable Member of the progress of the negotiations.

Medical Officers of the Territorial Force.

Sir FRANCIS LOWE asked the Financial Secretary to the War Office whether a doctor joining the Territorial Forces, although he might be of superior rank, got a much lower rate of pay than a doctor who joined Kitchener's army; and, if so, what was the reason for this inequality.—Mr. H. BAKER wrote in reply: It is true that certain civilian medical practitioners commissioned as temporary lieutenants R.A.M.C. received a consolidated rate of pay which is slightly higher than the amount of pay and allowances received by a captain of the Regular or Territorial Force R.A.M.C. It is sometimes necessary to give higher rates to those commissioned on emergency.

THURSDAY, APRIL 22ND.

Medical Officers of the Territorial Force.

Mr. WALTER GUINNESS asked the Financial Secretary to the War Office whether, in view of the sense of injustice caused by the increased rates of pay now given to medical men joining the Royal Army Medical Corps as lieutenants for the period of the war, all lieutenants in the Royal Army Medical Corps, Territorial Force, who were called out on mobilisation and who were now serving on 10*s.* a day less pay than men now joining at the same rank, might at once be promoted to the rank of captain, as had recently been done in the case of all lieutenants in the Regular Royal Army Medical Corps.—Mr. H. BAKER answered: The position of these officers is now under consideration. I may add that the difference in emoluments is not as suggested by the honourable Member.

Mr. W. GUINNESS: Is the honourable gentleman aware that the medical officers of the Territorial Force made great financial sacrifices and had to leave valuable practices at a moment's notice; and is he further aware that those medical officers are much older than officers of corresponding rank in the Regular Army Medical Corps, and naturally cannot look forward to a sufficient length of embodied service to qualify for a pension?—Mr. H. BAKER: I quite agree with the honourable gentleman that they have made great sacrifices, and the case is under consideration.

Indian Medical Service.

Sir PHILIP MAGNUS asked the Under Secretary of State for India whether he was aware that a number of officers in the Indian Medical Service, now actually serving in France with the field ambulances of the Indian Expeditionary Force, were drawing unemployed pay; and whether he would take steps at an early date to discontinue the arrangement under which many officers on active service were classed as unemployed and paid at the unemployed rate.—Mr. CHARLES ROBERTS replied: Unemployed pay is a somewhat misleading term. The salary of an Indian Medical Service officer holding a specific appointment is made up of grade pay and staff pay. Unemployed pay is the rate of pay allowed to a junior officer who has not yet obtained a specific appointment and is higher than the grade pay which he would otherwise receive. Under Orders recently passed all Indian Medical Service officers of two years' service and a good many others will, while on active service, receive as a minimum a rate of pay somewhat in excess of unemployed pay.

Sir P. MAGNUS: Will the honourable gentleman inquire as to why members of the Indian Medical Service are complaining very strongly of disabilities in many directions as compared with British medical officers, and will he take some steps to remedy this grievance?—Mr. C. ROBERTS: This is a technical matter. I should be very glad to look into it with the help of the honourable Member.

Mr. RAWLINSON: Will there be an opportunity given to discuss this question any time during the next few weeks? It is rather pressing.—Mr. C. ROBERTS: I shall see.

The Appointment of Dentists to Camps.

Mr. BRIDGEMAN asked the Financial Secretary to the War Office whether any appointments as dentists to the proposed camp at Park Hall, Oswestry, had been made, and if so, who were the dentists appointed and by whom had the appointments been made.—Mr. H. BAKER wrote in reply: No appointments have been made by the War Office, but the local military authorities have full power to employ local dentists should their services be necessary.

The Work of the Royal Army Medical Corps at the Front.

In the course of the debate on Army Estimates in Committee of Supply,

Mr. TENNANT (Under Secretary for War) said: When you consider the kind of warfare which we have been waging, and particularly when you consider the kind of weather in which it has been waged, the health of the troops has been remarkable. All epidemic diseases, such as measles or enteric fever, have been so brought under control as to enable us to circumscribe their area and to localise them at the earliest possible moment, whilst special illnesses to which the troops were particularly prone, such as frost-bite, have been so treated in the early stages that where actual prevention has not been effected, recovery in the shortest possible time has been general. To this the Field-Marshal Commanding-in-Chief has drawn attention in his latest despatch. I have before now laid special emphasis upon the sanitary arrangements of the responsible officers in the Royal Army Medical Corps. Again I would say that nothing could exceed the efficiency of the precautions they have taken or of the corps itself. Indeed, I think the absence of disease is the greatest and most eloquent tribute in their praise. To those who have knowledge of the diseases of warfare, when I mention this fact that there is not a single case of dysentery amongst our troops, it will be agreed, I think, that is one of the most significant things anyone can say. It is the same with regard to the arrangements for the care of the wounded, bringing them from the scene of active operations in the field to the clearing stations down to the base hospitals, and their transit in motor ambulances or hospital trains from those base hospitals to hospital ships and to this country, the arrangements for the treatment of wounds and disease both in France and at home—all these are subjects of legitimate pride and gratification. It was no uncommon feature of the battle of Neuve Chapelle that the wounded should be back at hospitals in London within 24 hours of their wounds having been received. I had the pleasure of seeing a lieutenant-colonel in one of the Highland regiments who was wounded at Neuve Chapelle, whilst in the trenches, between the hours of 1.30 at 2 o'clock in the afternoon. He became unconscious on receipt of his wound, and he awoke to consciousness soon after 3 o'clock in comfort in a bed in the hospital 11 miles behind the firing line, and with his wounds dressed. I think that is a most remarkable achievement. I mention these facts, which are well known to honourable Members in all parts of the House, because I believe them to be the broad outline of the picture as we see it to-day. I ask honourable Members never to forget that broad outline when they are endeavouring to fit in the details of their criticisms.

In a subsequent passage the Under Secretary said: Now that the rigors of winter may give place to the intensity of summer heat, we naturally are apprehensive that plagues of flies and insects may harass the troops, and we have sent out in order to combat that evil entomologists of world-wide reputation who are now engaged in trying to take such precautionary and preliminary steps as are possible while these creatures are in the larval stage to render the larvæ unlikely to bring forth the insects. At home bacteriologists have gone all over the country and have taken in hand individual cases of cerebro-spinal meningitis, which is a most dangerous disease and might prove a scourge in our ranks. I hope and believe that that difficulty has been successfully overcome.

Sanitary Preparations Urged.

Mr. WALTER LONG said that honourable Members all anticipated that the time was coming when our troops would advance over the country which was now occupied by the enemy. It appeared from all accounts that the condition of that country would be awful. There were now vast numbers of dead bodies, many of which were only partially buried. A great many churchyards had been destroyed by shell fire and dead bodies were exposed and would be exposed, and the general conditions would, he believed, be as awful as they well could be. It was possible, he was told, to take steps which would, if not destroy at all events modify very greatly the risk of the outbreak of a very bad epidemic. Every possible provision should be made in advance so that those evils could be overcome.

Colonel YATE remarked that he had just returned from France, where he had an opportunity of inspecting ambulance trains. The organisation and comfort which had now been introduced into them were deserving of all credit to those engaged in their management. A great many of the railway lines in France were single lines, and consequently the ambulance trains were often side-tracked for hours in order to allow munitions and men to pass up to the front. That was the only drawback, and he wished to say that the medical officers in charge of those trains were deserving of every credit for the way in which they had brought them to such perfection. He was sorry that he could not join with the right honourable gentleman (Mr. Tennant) in giving so much praise to the ambulance wagons. The drivers of these were not very experienced men, and often were rather rough. The way they drove the wounded over cobble stones and bad roads, without thought for the feelings and sufferings of the poor men inside, brought forth pity from those who saw it. It was a question that was very difficult to control. The best was being done possibly, but he did hope some steps would be taken to make those drivers drive as slowly and as comfortably as possible. The honourable and gallant gentleman called attention to the efficient and excellent management of the water ambulances. The ambulance flotilla was now working as a complete hospital with 200 beds, and was complete in every possible way. There were four barges accommodating 50 patients each, and there were doctors, a staff of nurses, an operating theatre, electric light, and all other conveniences. He trusted that as time went on the War Office would be able to introduce those hospital barges in much larger numbers in all the canals in Flanders and Northern France. There was no better way of transporting the wounded from the clearing station to the hospital ships than by barges, and he hoped that method would be largely extended.

Medical Officers of the Territorial Force.

Colonel GREIG raised the question of the position of medical officers of the Territorial regiments. He said many of these appointments had been filled by medical men who had given up large practices in order to go on service. As compared with other medical officers the Territorial medical officer seemed to be treated very badly. The facts were these. His period of service when he joined, for there was no limit, was as long as the authorities liked to keep him. His pay was 14*s*. per diem plus certain allowances. The highest possible amount he could get was 18*s*. 10*d*. per diem. When he started his work he got an outfit allowance of £30 and a camp outfit allowance of £7 10*s*., which everyone who knew about these matters was perfectly well aware did not cover the camp outfit cost. He got no gratuity at the end of his service. He wanted to compare their position with that of men who had joined the Royal Army Medical Corps. There were many cases of pupils who had been trained by present members of the Territorial Medical Corps, and when these Territorial medical officers met their old-time pupils in camp they found their pupils in higher ranks and receiving a very much higher rate of pay. The thing was an absurdity. The two sets of men were doing exactly the same work. Of course, the Territorial medical officers in a large number of cases had taken the Imperial Service obligation. The period of service of medical men who had accepted commissions in the Royal Army Medical Corps was 12 calendar months, or until their services would be no longer required, which presumably would be when the war had terminated. The pay was 24*s*. per diem, being a flat rate with no allowances. Travelling on duty was also paid for by the Government. This officer got an allowance of £30 at the time of joining the service, the same as the Territorial medical officer, but at the end of his service he got £60. It was a matter for consideration whether these two sets of men should not be put on the same footing, and whether the scale of pay of the Territorial medical officers should not be raised to that of the officers of the Royal Army Medical Corps

Mr. FALLE called attention to the position of majors of the Royal Army Medical Corps (Territorial). If these officers were attached to any unit but the medical unit they could not be promoted to the rank of lieutenant-colonel. When he said "could not" he meant that, although it had been done, it was very unusual. He knew one who had been attached to a Territorial regiment for more than 20 years, and he had gone through all the ranks up to that of major, but he had been told that he could not be promoted higher. That did not seem to be fair, considering that newcomers were promptly made lieutenant-colonels and received pay superior to the men who had been over 20 years with their regiments.

Mr. H. BAKER (Financial Secretary to the War Office) said, in the course of his reply to the debate: Reference has been made to the question of the hardships of doctors to the Territorial Forces. Well, they were well aware of the terms of the contract into which they entered, and they have suffered no hardship, but we should all recognise the very great sacrifices, possibly greater than those any other class have made, which these medical officers have made in giving up their practices and giving their services to the State. Something should be done with regard to promotions, and the question of a gratuity such as has been offered to medical officers especially enlisted after mobilisation on the outbreak of war is also under consideration and I hope will shortly be decided.

Tuesday, April 27th.

Promotions in the Royal Army Medical Corps.

Sir Henry Craik asked the Under Secretary for War whether officers of the Special Reserve of the Royal Army Medical Corps were being treated differently from the rest of that corps as regarded temporary promotion, and, if so, upon what grounds that difference was based.—Mr. Tennant replied: Temporary promotion is not given in the Regular Royal Army Medical Corps. In the Special Reserve Royal Army Medical Corps promotion is by time, but it is probable that some promotions otherwise than in respect of a period of service will be made.

Mr. T. M. Healy asked the right honourable gentleman whether the lieutenants of the regular Royal Army Medical Corps had all been promoted captains; and was it the intention of the Government to promote the lieutenants of the Special Reserve Royal Army Medical Corps, who were in the Special Reserve Royal Army Medical Corps before the outbreak of the war, giving them the same seniority as they had at mobilisation.—Mr. Tennant wrote in reply: The lieutenants of the Regular Royal Army Medical Corps have been promoted to the rank of captain to ensure as far as possible a due proportion of that rank to the large number of temporary lieutenants now serving. The position of the Special Reserve lieutenants is different. It is not the intention to promote all of these, but it is probable that the promotions of some will be made.

Medical Service at the Front.

Mr. Robinson asked the Under Secretary for War whether, in view of the strain imposed upon many doctors who had been at the front for several months, he would make use of the services of first-class medical men of the Royal Army Medical Corps now in this country anxious to do duty abroad, and thus relieve for a time those doctors abroad who had been toiling incessantly for months.—Mr. Tennant answered: I imagine that my honourable friend is referring to the temporary commissioned medical officers, and I can assure him that all those who are eligible for foreign service will take their turn at the front.

Sanatorium Treatment for Soldiers.

Sir Henry Craik asked the Under Secretary for War whether provision would be made systematically for the sanatorium treatment of soldiers suffering from consumption or tuberculosis caused by hardships experienced on active service or developed as the result of wounds; whether he was aware that at present such provision was casual only and in some cases entirely wanting, and that offers of accommodation in consumption hospitals had been sometimes accepted and sometimes declined by the Medical Department of the War Office upon no apparent uniformity of principle; and who was responsible for this state of matters.—Mr. Tennant said in reply: I fully recognise the importance of this matter, to which careful attention has been given. The National Health Insurance Commissioners accept the responsibility to secure the provision of accommodation in sanatoriums of all cases of tuberculosis amongst insured soldiers. Instructions to this effect, and as to the procedure to be followed, have recently been issued to all commands. The best method of providing sanatorium treatment for tuberculous soldiers who are not insured is not yet finally settled, but the War Office has taken up and has at its disposal beds in several sanatoriums, and full use has been made of these. Only one offer of a consumption hospital has been refused. This was because the War Office were advised that it was not suitable for military cases.

Wednesday, April 28th.

Medical Consultants to the Admiralty.

Commander Bellairs asked the Secretary to the Admiralty whether any sums of over £3000 a year were being paid to doctors and surgeons in civil life as retainers for their services; if so, in what cases and what amounts; and whether the arrangement was made prior to the war and allowed of private practice as well.—Mr. Macnamara furnished the following written answer: The following consultants are paid over £3000 per annum: Cheatle, G. L., Esq., C.B., C.V.O., F.R.C.S., £5000 per annum; Cheyne, Sir W. W., Bart., C.B., F.R.C.S., £5000 per annum; Johnson, Raymond, Esq., M.B., F.R.C.S., £5000 per annum; Macewen, Sir W., F.R.C.S., £5000 per annum; Rolleston, H. D., Esq., M.D., F.R.C.S., £5000 per annum; Turner, G. R., Esq., F.R.C.S., £5000 per annum. The employment of eight consultants was approved previous to the outbreak of war. The whole time of these consultants is at the disposal of the Admiralty, and they are under similar regulations with regard to private practice as all other medical officers serving—viz., private practice is not forbidden, but must not in any way interfere with the performance of an officer's naval duties.

Spotted Fever in Middlesex.

Sir J. D. Rees asked the Parliamentary Secretary to the Local Government Board whether any cases of spotted fever had occurred in Middlesex; and, if so, whether special attention had been called, in the localities affected, to the circular on this subject issued by the Board.—Mr. Herbert Lewis wrote in reply: Some cases have occurred, and one of the Board's medical inspectors was instructed to confer with officers of the county council and district councils.

Appointments.

Successful applicants for vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward to The Lancet *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week, such information for gratuitous publication.*

Fisher, A. G. T., L.R.C.P. Lond., M.R.C.S., has been appointed Senior Resident Officer at the Bristol General Hospital.

Green, Reginald, M.D., B.S., D.Hy., D.P.H. Durh., has been appointed Deputy Medical Officer of Health for the East Gloucestershire Combined District.

O'Donnell, T., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Northleach District of the county of Gloucester.

Procter, G. W., M.B. Durh., L.R.C.P. Lond., M.R.C.S., has been appointed Certifying Surgeon under the Factory and Workshop Acts for the Garston District of Liverpool.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

When the application of a Belgian medical man would be considered the advertisers are requested to communicate with the Editor.

Abergavenny, Monmouth County Asylum.—Temporary Assistant Medical Officer. Salary £7 7s. per week, with board, apartments, and attendance.

Anglo-Serbian Hospital, Urnjatchka, Benja, Serbia.—Surgeon.

Birkenhead Borough Hospital.—Female Senior and Junior House Surgeons. Salary £180 and £150 per annum respectively, with board and laundry.

Birmingham General Dispensary.—Resident Medical Officer, unmarried. Salary £250 per annum, with apartments, attendance, &c.

Bolton Infirmary and Dispensary.—Third House Surgeon. Salary £170 per annum, with apartments, board, and attendance.

Bournemouth, Royal Victoria and West Hants Hospital.—House Surgeon for six months. Salary £100 per annum, with board, lodging, washing, &c.

Brentwood Asylum, Brentwood, Essex.—Locum Tenens Assistant Medical Officer. Salary £6 6s. per week, with board, attendance, lodging, and washing.

Bristol, Beaufort War Hospital.—Chief Resident Surgeon. Also Resident Physician and Surgeon.

Bristol General Hospital.—Second House Physician, House Surgeon, Casualty House Surgeon, and Resident Obstetric Officer, all for six months. Salary at rate of £150 per annum, with board, residence, &c.

Bristol Royal Hospital for Sick Children and Women.—Junior Resident Officer. Salary £100 per annum, with board, rooms, attendance, and laundry.

Bristol Royal Infirmary.—Three House Surgeons, Two House Physicians, and One Obstetric and Ophthalmic House Surgeon. Salary at rate of £120 per annum, with board, apartments, and laundry.

Burnley, Victoria Hospital.—House Surgeon. Salary £135 per annum, with residence, board, and washing.

Bury Infirmary.—Senior and Junior House Surgeons. Salary £175 and £150 per annum respectively, with board, residence, and washing.

Buxton, Derbyshire, Devonshire Hospital.—Assistant House Physician for six months. Salary £100 per annum, with apartments, board, and laundry.

Cardiff, King Edward VII.'s Hospital.—Resident Surgical Officer. Salary £160 per annum, with board, laundry, and apartments.

Cardiff, Welsh Metropolitan Military Hospital, Whitchurch.—Chief Resident Surgeon and Chief Resident Physician. Salary £1 3*s.* 6*d.* a day, with board, lodging, &c.

Carlisle Non-Provident Dispensary.—Resident Medical Officer. Salary £200 per annum, with apartments (not board).

Carmarthen, Joint Counties Asylum.—Temporary Second Assistant Medical Officer. Salary at rate of £200 per annum, with board, lodging, washing, &c.

Cheshire County Council.—District Tuberculosis Officer. Salary £350 per annum.

City of London Hospital for Diseases of the Chest, Victoria Park, E.—House Physician. Salary as agreed, with board, residence, and washing.

City of London Lying-in Hospital, City-road, E.C.—Resident Medical Officer for four months. Salary at rate of £50 per annum, with board, lodging, and washing.

Derby, Derbyshire Royal Infirmary.—House Physician and Casualty Officer. Salary £250 per annum, with board, residence, &c.

Derbyshire Education Committee.—Temporary Female Assistant School Medical Officers. Salary £400 per annum, inclusive.

East Sussex County Council.—Female Inspector of Midwives and Child-Welfare. Salary £190 per annum.

Epsom, County of London War Hospital.—Chief Resident Physician, Resident Radiographer, and Resident Dental Surgeon. Also, on the Visiting Staff, Physicians and Surgeons to take charge of wards, Operating Surgeons, Ophthalmologist, Aural Surgeon, Dermatologist, and Radiographer.

Epsom, London County Asylum, Long Grove.—Locum Tenens Medical Officer. Salary 6 guineas a week, with quarters, board, and washing.

Folkestone, Royal Victoria Hospital.—House Surgeon. Board, residence, and laundry, and salary as arranged.

Gravesend Hospital.—House Surgeon. Liberal salary, with board, residence, and washing.

Greenwich Union Infirmary and Workhouse.—Junior Assistant Medical Officer. Salary £175 per annum, with apartments, rations, and washing.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages, and Deaths.

Notes, Short Comments, and Answers to Correspondents.

ALCOHOLIC LIQUORS.

THE orders issued by the King and Lord Kitchener have caused a large amount of comment in the press, both editorial and from organisations and societies, as well as from private individuals, and the Chancellor of the Exchequer has been inundated with a gigantic, but invited, correspondence on the subject of taking a special pledge of abstention from alcoholic liquors during the war. The question has many sides—the question of the preservation of the State, the preservation of trade (including that of the licensed trade), the preservation of employment, the saving of life, the saving of time, the saving of money, and the preservation of the public health. Some maintain that if we abolished whisky during the war we should be falling into line with the ban on absinthe in France and on vodka in Russia. The claim is that raw spirits do most harm, especially in the north. This was the opinion of the renowned Dr. Benjamin Rush, whose articles on the use of spirits, published about 1785, are said to have caused the establishment in America of the first anti-spirit association or temperance society. The titles of his writings were: "An Inquiry into the Effects of Spirituous Liquors upon the Human Body, and Their Influence upon the Happiness of Society," 11 pages, published at Philadelphia; and "An Inquiry into the Effects of Ardent Spirits upon the Human Body and Mind, with an Account of the Means in Preventing and of the Remedies for Curing Them." The sixth edition of this was published at New York by C. Davis in 1811, and there were subsequent editions at Boston.

THE DEFINITION OF A CONSULTANT.

To the Editor of THE LANCET.

SIR,—Can any of your readers give me a definition of a consultant? or a short résumé of the rules that are supposed to govern his conduct?

I am, Sir, yours faithfully,
April 23rd, 1915. ENQUIRER.

WOMEN AND THEIR WORK EXHIBITION.

FROM May 1st to 7th, at the Royal Horticultural Hall, Vincent-square, Westminster, an exhibition, organised by the *Daily Express* and under the patronage of Queen Alexandra, Princess Arthur of Connaught, and the Duchess of Teck, will be held with the object of showing what work women are doing, what occupations are open to them, and, incidentally, what work is unsuitable for women as a permanent occupation. It is hoped, also, that ideas will be suggested enabling women to plan for themselves new means of earning a livelihood. The scope of the exhibition will be so wide as to include the rough work of farming and the more delicate manipulation necessary in jewellery making. One exhibit will show a ward of the Middlesex Hospital, lectures will be given by Dr. Elizabeth Sloan Chesser, and invalid kitchens will be shown by Lady Muriel Paget.

AN ANCIENT ROMAN MEDICAL MAGISTRATE.

IN the Italian record of archæological discoveries for the year 1913 Signor A. Neomatini and Signor A. Aurigemma publish an honorific inscription of the year A.D. 213, found near Beneventune, which restores to medical history the name of an ancient Roman physician who practised in that city. His name was L. Staius Manilianus, but he retained also an additional cognomen, that of Acesius, from his grandparents. He was evidently greatly respected by his fellow citizens, for he held the municipal post of *Prætor Cerealis iure dicendo quinquennalis*, and presented a *sparsio* to the populace in acknowledgement of the trust thus placed in him.

A HANGING MATTER.

A CORK correspondent calls our attention to the fact that in the press accounts of the hanging of the Egyptian assassin it is stated that the execution "went off without a hitch"—truly, he says, a queer sort of *hanging*.

URO-HEXOIDS.

THE British Drug Houses, Limited, of 22–30, Graham-street, City-road, London, N., announce that their tablets formerly known as "Urosolvene" are now to be designated as "Uro-hexoids." As was pointed out in an analytical record published in THE LANCET of Jan. 2nd, 1915, this is a combination of hexamine and lithium benzoate used as a uric acid solvent and urinary antiseptic.

THE VALUE OF A UNIFORM.

AT the Free Library of St. Martin-in-the-Fields, Trafalgar-square, notices have been posted outside the building saying that soldiers, sailors, and nurses in uniform can receive facilities and free stationery within on application to the attendant. The first offer should afford encouragement to ask for what is wanted, whatever it may be. We should like to see a similar attitude adopted in other public places. There are few facilities for writing in the ordinary refreshment-room, and a note written by soldier, sailor, or nurse to those at home would often be highly valued by relatives, and in some cases would assist the medical man to sustain those there who are depressed when left long without news of their relatives and friends in the services. The value of the uniform is being more and more shown as a *passe-partout*.

PHOTOMICROGRAPHY.

UNDER this title Kodak, Limited, of Kingsway, London, W.C., have issued, at the price of 3*d*., the third edition of an illustrated pamphlet, forming one of a series, and intended principally for the use of beginners in photomicrography. It discusses the apparatus required, explains the method of illumination, the use of coloured filters, photographic procedure and development, and cognate matters in an expository rather than a scientific style.

B. R.—The Coroners Act, 1887, Section 22, which prescribes the fees which a medical practitioner summoned as a witness at an inquest shall be entitled to receive, provides that where an inquest is held on the body of a person who has died in a public hospital (or other institution specified) the medical officer whose duty it may have been to attend the deceased person as a medical officer of such institution "shall not be entitled to such fee or remuneration." The Act makes no exception with regard to a post-mortem examination performed by order of the coroner, and, therefore, if any fee is paid to the officer as above defined in respect of such examination and of the evidence based upon it, this must be through recognition by the coroner and of those who provide the fees of what is just and right, and not because the witness is entitled by the Act to claim payment.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

SOCIETIES.

ROYAL SOCIETY, Burlington House, London, W.

THURSDAY.—Mr. G. W. Walker: Some Problems illustrating the Forms of Nebulæ.—Hon. R. J. Strutt: Observations on the Resonance Radiation of Sodium Vapour.—Hertha Ayrton: Local Differences of Pressure near an Obstacle in Oscillating Water (communicated by Lord Rayleigh, O.M.).—Mr. J. H. Brinkworth: Measurement of the Specific Heat of Steam at Atmospheric Pressure and 104·5° C., with a Preface by Prof. H. L. Callendar (communicated by Prof. H. L. Callendar).—Mr. C. F. Jenkin and Mr. D. R. Pye: Thermal Properties of Carbonic Acid at Low Temperatures. II. (communicated by Sir Alfred Ewing).

ROYAL SOCIETY OF MEDICINE, 1, Wimpole-street, W.

TUESDAY.

SECTION OF SURGERY: SUB-SECTION OF ORTHOPÆDICS (Hon. Secretaries—A. S. Blundell Bankart, E. Rock Carling): at 5 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1915–1916.

SECTION OF PATHOLOGY (Hon. Secretaries—Gordon W. Goodhart, C. Price-Jones): at 8.30 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1915–1916.

Dr. Charlton Bastian, F.R.S.: The Importance of Tyrosine as an Aid in the Demonstration of the Present Day *de novo* Origin of Living Organisms.

Dr. Hingston Fox: Aneurysm of Left Ventricle.

THURSDAY.

SECTION OF OBSTETRICS AND GYNÆCOLOGY (Hon. Secretaries—C. Hubert Roberts, Cuthbert Lockyer): at 8 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1915–1916.

Specimens:

Dr. J. Bright Banister: (1) Twisted Omentum Simulating Twisted Ovarian Cyst; (2) Placental Attachment to Fœtal Head.

Dr. T. G. Stevens: Case of Rhabdo-myoma of the Vulva.

Mr. W. Gilliatt: Viscera from Fatal Case of Eclampsia.

Dr. C. E. Purslow: Tubal Pregnancy showing Fœtus undergoing Dissolution.

Short Communications:

Mr. Douglas Drew: Complete Inversion of the Vagina after Hysterectomy (12 years) associated with Vesical Calculus.

Dr. R. Drummond Maxwell: Diphtheritic Stenosis of the Vagina.

Dr. W. Blair Bell: Infundibulin in Primary Uterine Inertia and in the Induction of Labour.

Papers:

Dr. W. Blair Bell: So-called True Hermaphroditism.

Dr. T. G. Stevens: Adenomyoma of the Recto-Vaginal Septum.

FRIDAY.

SECTION OF LARYNGOLOGY (Hon. Secretaries—Cecil I. Graham, W. D. Harmer): at 5 P.M.

Annual General Meeting.—Election of Officers and Council for Session 1915-1916.

In addition to the usual cases and specimens there will be a Special Exhibition of War Injuries and Neuroses which have come under the care of various Members of the Section at 4 P.M.

ROYAL SOCIETY OF ARTS, John-street, Adelphi, W.C.

ROYAL INSTITUTION OF GREAT BRITAIN, Albemarle-street Piccadilly, W.

TUESDAY.—3 P.M., Prof. C. S. Sherrington: The Animal Spirits. (Lecture I.)

For further particulars of the above Lectures, &c., see Advertisement Pages.

EDITORIAL NOTICES.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITOR," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention should be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this office.

Lectures, original articles, and reports should be written on one side of the paper only, AND WHEN ACCOMPANIED BY BLOCKS IT IS REQUESTED THAT THE NAME OF THE AUTHOR, AND IF POSSIBLE OF THE ARTICLE, SHOULD BE WRITTEN ON THE BLOCKS TO FACILITATE IDENTIFICATION.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers—not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICES.

TO SUBSCRIBERS.

WILL Subscribers please note that only those subscriptions which are sent direct to the Proprietors of THE LANCET at their Offices, 423, Strand, London, W.C., are dealt with by them? Subscriptions paid to London or to local newsagents (with none of whom have the Proprietors any connexion whatever) do not reach THE LANCET Offices, and consequently inquiries concerning missing copies, &c., should be sent to the Agent to whom the subscription is paid, and *not* to THE LANCET Offices.

Subscribers, by sending their subscriptions direct to THE LANCET Offices, will ensure regularity in the despatch of their Journals and an earlier delivery than the majority of Agents are able to effect.

THE COLONIAL AND FOREIGN EDITION (printed on thin paper) is published in time to catch the weekly Friday mails to all parts of the world.

The rates of subscriptions, post free from THE LANCET Offices, have been reduced, and are now as follows:—

FOR THE UNITED KINGDOM.		TO THE COLONIES AND ABROAD.	
One Year	£1 1 0	One Year	£1 5 0
Six Months	0 12 6	Six Months	0 14 0
Three Months	0 6 6	Three Months	0 7 0

(The rate for the United Kingdom will apply also to Medical Subordinates in India whose rates of pay, including allowances, is less than Rs.50 per month.)

Subscriptions (which may commence at any time) are payable in advance. Cheques and Post Office Orders (crossed "London County and Westminster Bank, Covent Garden Branch") should be made payable to the Manager, Mr. CHARLES GOOD, THE LANCET Offices, 423, Strand, London, W.C.

TO COLONIAL AND FOREIGN SUBSCRIBERS.

SUBSCRIBERS ABROAD ARE PARTICULARLY REQUESTED TO NOTE THE RATES OF SUBSCRIPTIONS GIVEN ABOVE.

The Manager will be pleased to forward copies direct from the Offices to places abroad at the above rates, whatever be the weight of any of the copies so supplied.

SOLE AGENTS FOR AMERICA—MESSRS. WILLIAM WOOD AND CO., 51, Fifth Avenue, New York, U.S.A.

Remarks
ON
ARTERIO-VENOUS ANEURYSM.

Made at a Symposium[1] on the Subject at Radcliffe Infirmary, Oxford, on March 26th, 1915,

BY SIR WILLIAM OSLER, BART., M.D., F.R.S.,
REGIUS PROFESSOR OF MEDICINE IN THE UNIVERSITY OF OXFORD.

GENTLEMEN,—Better than any other disease aneurysm illustrates how borderless are the boundaries of medicine and surgery. Here am I talking on the most surgical of all its aspects, while very likely not far away a surgeon is practising the best possible prevention against internal aneurysm in giving a syphilitic patient an injection of salvarsan! Aneurysm has been a medico-chirurgical affection ever since some bungling young "minutor" first nicked the brachial artery in performing venesection. One of the earliest and most interesting references in literature is to an instance of this kind. Galen was called in consultation by a young and inexperienced surgeon who had opened the artery at the bend of the elbow instead of the vein, and the blood spurted out "clarus, rubens, lucidus et calidus."

> "I took in the situation at once; there happened to be an elderly physician with me, so we prepared a medicine, viscid, conglutinable, and obstructive, and placing it strongly against the lips of the wound bound over it a soft sponge. The surgeon who had opened the artery wondered, but said nothing. When we went out"—note the professional touch!—"I said to the surgeon that he had opened the pulsating vessel, and charged him not to dress the wound before the fourth day, and not without me."

The cure was complete, and Galen remarks that this was his only successful case of the kind, as in all others aneurysm had followed. This account, taken from Symphorien Campegius "Claudii Galeni Pergameni Historiales Campi, Basilae," 1532, p. 43, is doubtless of the case referred to in the "Methodus Medendi."[2] The only other references to aneurysm in Galen are in the "De Tumoribus praeter Naturam"[3] and in the "De Curandi Ratione per Sanguinis Missionem,"[4] in which he refers to the possibility of gangrene.

HISTORICAL SURVEY.

Rational surgery was one of the gifts of the Greeks, but in the 800 years between Hippocrates and Oribasius few names have survived specially associated with this branch of medicine. Who among us off-hand could recall more than two or three in addition to Hippocrates and Galen? Yet in this period scores of important schools flourished with great teachers of surgery, men honoured in their generation and the glory of their times. As one reads the partial list in Haller's "Bibliotheca Chirurgica" and scans the few golden remains of their writings fortunately preserved by encyclopædists such as Oribasius and Paul of Ægina, the truth of Sir Thomas Browne's remarks comes home: "Who knows whether the best of men be known, whether there be not more remarkable persons forgot than any that stand remembered in the known account of time?" Two of these comparatively unknown men created the surgery of arteries, Rufus of Ephesus and Antyllus, the Cosmas and Damien of Greek surgery.[5]

Rufus of Ephesus.

To generations of practitioners unworthy to hand him ligatures Rufus of Ephesus (Reign of Trajan, early part of second century A.D.) was known by the "pilulæ Ruffi," "the pills I would not be without"—"pilulæ sine quibus esse nolo"—still in the British Pharmacopœia as the pill of aloes and myrrh. In the brilliant Ionian profession of the early days of our era Rufus doubtless had predecessors and teachers, but he stands out a strong, clear figure, a great "magister chirurgiæ," a title justly earned by his remarkable contribution to the surgery of hæmostasis. We know it only through a section in Aetius, a sixth-century physician.[6] Nothing is lacking in a description, which might be transferred to any modern text-book—digital compression, styptics, the cautery, torsion, and the ligature—only I am sorry not to find, as is sometimes said, a description suggestive of arterio-venous aneurysm, though he speaks of the possibility of traumatic aneurysm.

Through the Arabians the name of Rufus was on the lips of every mediæval physician, and we find him among the favourites of Chaucer's well-read Doctor. In one of the earliest and most beautiful of medical manuscripts, the famous "Juliana Anicia Dioscorides" (A.D. 525), of the Vienna Library, he is figured with Galen, Hippocrates, and others.

Antyllus.

Upon the other great surgical figure of antiquity, Antyllus, so blindly has oblivion scattered her poppies, to quote Sir Thomas Browne again, that not a fact of his life is known; yet through the mists of 18 centuries he looms large as one of the most daring and accomplished surgeons of all time. A resector of bones and joints, one of the first to perform tracheotomy, the founder of the surgery of fistula, a successful operator upon cataract, and we may say the creator of the surgery of the arteries—these are among his known achievements. His remains are chiefly in the works of Oribasius, the physician and friend of the Emperor Julian.

Nowhere are we impressed with the note of directness so characteristic of the Greek (see R. W. Livingstone's "Meaning of the Greek Genius," second edition, 1915) as in the brilliant account given by this author of aneurysm, of which he was the first to recognise two forms—one by dilatation, the other following wound of the artery. So far as I can gather, he was also the first to describe the thrill or bruit so characteristic of the latter form. No ancient writer has anything like the same accuracy of pathological description, and you may search the surgical literature for centuries before there is found such a gem as the account of his method of operation still in use, and by which his name has been permanently enshrined. Not finding one in English, I asked Mr. Livingstone, of Corpus Christi College, to give us a complete translation of the fragment.

About Aneurysms (from the works of Antyllus[7]).

There are two different kinds of aneurysms. The one kind occurs when there is a local dilatation of an artery (this

[2] Linacre's edition, 1517, f. lxii., v.

[3] Junta, fifth edition, 1576, iii., p. 84.

[4] Ibid., vi., p. 21.

[5] These practitioners, who became the Christian saints of surgery, suffered martyrdom in Cilicia in the third century. In their Western Mother Church, on the Roman Forum, I have seen the little parcel said to contain the instruments with which they performed the most famous operation in hagiological surgery, substitution of the healthy thigh of a just-dead man for one that was gangrenous.

No. 4784.

> was the origin of the name aneurysm or dilatation). The other kind arises from the rupture of an artery and the discharge of the blood into the flesh beneath it. Aneurysms due to the dilatation of an artery are longer than others; those due to a rupture are rounder. In the former there is a thicker layer of tissue; in the latter you can hear a certain crepitation if you press them with your finger; while in aneurysms due to dilatation there is no sound.
>
> It is foolish to follow the practice of the ancient surgeons and decline to treat any aneurysm, but it is dangerous to apply surgical treatment to all types. So we will excuse ourselves from treating aneurysms in the armpit, groin, and neck on the ground that the vessels are large and that it is impossible or dangerous to isolate and tie them. We also decline exceptionally big aneurysms, even if they occur elsewhere. But we will operate as follows on aneurysms in the extremities, the limbs and the head.
>
> If the aneurysm results from dilatation, we will make a straight incision in the skin the whole length of the vessel; then, after separating the edges of the incision with hooks, we will carefully sever all the membranes between the skin and the artery. Then pushing aside with blunt hooks the vein adjacent to the artery, we will expose the dilated portion of the artery on all sides. Next, we will introduce the head of a probe underneath, and, lifting the aneurysm, insert along the probe a needle with a double thread, so that it passes beneath the artery. We will cut the thread at the eye of the needle, making two threads and four ends of thread; then, taking the two ends of one of the threads, we will pass them gently to one end of the aneurysm and tie them with precision. Similarly, we will pass the other thread to the opposite end of the aneurysm, and then tie up the artery, so that the entire aneurysm lies between the two ligatures. Then we will lance the aneurysm with a small incision at its centre; in this way its contents will all be evacuated without any danger of hæmorrhage. Those who tie the artery, as I advise, at each extremity, but amputate the intervening dilated part, perform a dangerous operation. The violent tension of the arterial pneuma often displaces the ligatures.
>
> If the aneurysm originates in the rupture of an artery, isolate with your fingers as much of the aneurysm as you can, including the skin. Then below the isolated part introduce a needle with a double thread of flax or of gut; after passing it through cut it at the needle's eye, forming two threads. Take hold of the two ends of one of these and pass it to the right, there tie it tightly, so as not to slip. Pass the other end similarly in the opposite direction—to the left. If there is any fear of the threads slipping, pass a second needle with a similar double thread through the same spot, intersecting the first thread and crossing it in the form of the letter χ (chi). Cut the threads as before, and tie them like the first ones, so that four threads form the ligature. Then open the tumour at its top, and, after evacuating the contents, remove the superfluous skin, leaving the part tied by the threads. In this way the operation is effected without hæmorrhage.

And I must read Mr. Livingstone's comment:—

> It certainly is a beautiful piece of lucid writing. I felt that if I was alone on a desert island with someone suffering from aneurysm, and the tide had washed ashore sufficient *ἄγκιστρα*, &c., that I shouldn't have minded trying the operation. And Antyllus had real literary power. What an admirable phrase is *ἐκπτύεται*, the "spitting out" of the ligature by the throbbing artery: I don't think you can get it in English, and I fell back on a lame substitute, "displaces."

Not unjustly does Paul Broca in his great monograph, "Des Anévrismes," claim that not only did Antyllus create operative medicine but the pathology of aneurysm: "À chaque ligne on reconnait l'écrivain qui parle de ce qu'il a vu, de ce qu'il a fait."

Decay and Revival of Vascular Surgery.

Aetius in the middle of the sixth century describes the method for cure of aneurysm at the elbow, known later as that of Anel (1710), ligation of the brachial artery three or four fingers'-breadth below the axilla, followed by opening the sac, which was allowed to heal by suppuration. A curious error of Sprengel has led to the connexion of the name of Philagrius, a fourth century surgeon, with this operation. In the fragments of this writer given by Aetius aneurysm is not mentioned, but Sprengel never noticed that the extract on aneurysm which follows directly after one upon ganglion by Philagrius did not belong to this author but to Aetius himself.

A casual perusal of the fragments of the Greek surgeons of the first three or four centuries of our era as given in Gurlt's "Geschichte der Chirurgie" gives the impression of a great and fruitful period with scores of men whose qualifications were those demanded by Thomas Fuller for the good operator—the eagle's eye, the lion's heart, and the lady's hand. Then came the tragedy, the death in the West of the science of the Greeks. The Church took over their philosophy, the Arabs absorbed much of the best of their medicine and added to it, but surgery as a progressive science and a successful art died with its founders, the great Greeks of the Græco-Roman Empire. So far as the surgery of arteries is concerned we might take a jump of a thousand years or more were it not for an Arabian, Albucasis of Cordova (tenth century), who wrote a famous surgical treatise, of which we have in the Bodleian the two earliest manuscripts. A young scholar of Wadham and student of Christ Church, John Channing, in 1778 issued from the Clarendon Press a beautiful edition. The description which he gives of aneurysm with its treatment is practically that of Antyllus. He notes the stridor to be felt, which indicates that he was probably dealing with the arterio-venous form.

In vascular surgery the men of the Middle Ages and of the Renaissance, Henri de Mondeville, Guy de Chauliac, and even Ambroise Paré, were blind followers, who never even approached the position of their masters. Not much more than a century has passed since men of the John Hunter type took up vascular surgery where Rufus and Antyllus had left it, and only to this generation of experimental surgeons, such as Eck, Ballance, Matas, J. B. Murphy, Halsted, Carrel, and Guthrie, could the best of the Greeks go to school. You may think perhaps, that I am scarcely just to the great mediæval surgeons, particularly to such a master as Ambroise Paré, who reintroduced the ligature, but in vascular surgery, the touchstone of the position of the art, they never wholly regained what the profession had lost.

Our modern knowledge dates from William Hunter, in whose "Medical Observations and Enquiries,"[8] in a paper on Aneurysm of the Aorta he asks, "Does it ever happen in surgery when an artery is opened through a vein that communication or anastomosis is afterwards kept up between the two vessels?" He then describes, in a case following bleeding, the swelling, enlargement of the veins, and "a tremulous jarring motion" strongest at the part that had been punctured. In a subsequent paper, 1761,[9] he described two cases very fully, and recognised the enlargement of the arteries and of the veins and the characteristic hissing noise "as if there was a blast of air through a small hole and interrupted, answering precisely and constantly to the stroke of the heart or diastole of the artery."

It is true that in the seventeenth century Sennertus, the distinguished Wittenberg professor, noted in this form of aneurysm the characteristic thrill which he compares to the boiling of water, "quasi bullientes aquae," not only palpable but audible, as if the vital spirits were passing through a narrow orifice.[10]

[9] Further Observations upon a particular Species of Aneurysm, Medical Observations and Enquiries, London, 1761.

RARITY OF ARTERIO-VENOUS ANEURYSM.

It is remarkable how few specimens of arterio-venous aneurysm of the external vessels are in the museums of this country. I have only been able to get references to some half dozen cases. One is astonished not to find any in the Army Medical Museum, Millbank, or at Haslar or Greenwich. Nor is there an example in William Hunter's Museum at Glasgow. The Royal College of Surgeons of England has only three, including a recent uncatalogued one sent by Sir G. H. Makins. Its most remarkable specimen was sent in 1867 by Dr. Beaumont, of Toronto, an old teacher of mine. I was not a little surprised and greatly pleased to find a pathological memorial of this fine old St. Bartholomew's man, a fellow pupil of Paget, who went out to Toronto in the early "forties" and became professor of surgery in the newly founded King's College. It is an admirable specimen as illustrating the late changes in the veins. The case is fully described by Beaumont in the *Medical Times and Gazette* for July, 1867. A man, aged 45, had 11 years previously been stabbed in the upper part of the thigh. There was a very large pulsating tumour in the upper part of the right thigh, fully six inches in extent in either direction and extending nearly to Poupart's ligament. The patient died under chloroform, which was administered for the purpose of ligaturing the external iliac artery. The specimen shows a venous sac as big as a small cocoanut, measuring 14½ by 12½ inches, very thin walls containing some old laminated fibrin, and the walls were in places calcified.

The truth is, this is not a country of brawls and dirks, and pistol wounds are rare in civil life. It is strange that no specimens found their way to the museums from the South African War. The Army Medical Museum, Washington, has only two examples (Lamb).

The rarest of all forms, arterio-venous aneurysm, is occasionally met with in the medical clinic as when a small aortic aneurysm opens into the superior vena cava, while on the surgical side trauma is responsible for 99 per cent. of those connected with the external vessels. Until the recent wars stab wounds accounted for the large majority of cases, but in the Japanese, the South African, and the Serbian wars the high-velocity bullet heads the list of causes.

PERSONAL EXPERIENCE OF WOUNDS OF ARTERIES.

Naturally, as a physician my experience with wounds of arteries has been very limited—until recently only 10 cases, in 5 of which arterio-venous aneurysm followed. The other 5 cases came in medico-legal post-mortem work in Montreal, and they may be just mentioned for their interest.

1. A soldier during the vaccination riots in Montreal gave a man a prod with his bayonet, which passed through the top of the left lung and cut the subclavian artery just as it leaves the arch to curve over the pleura.
2. A man in a brawl received a stab with a penknife at the root of the neck, followed by a traumatic aneurysm, which was operated upon unsuccessfully; the tip of the knife had cut the vertebral artery between the lateral processes of the fifth and sixth cervical vertebræ.
3. A man received a blow on the head in a tussle, and some days later died suddenly of hæmorrhage from the nose; a fracture of the sphenoid was found with laceration, or erosion, of the internal carotid just where it turns into the sella turcica.
4. A man in riding jerked against the pommel of his saddle and drove a dirk which he was carrying into his femoral artery.
5. A fatal bullet wound of the left internal iliac artery.

The arterio-venous cases I will quote in connexion with their most striking features. Within a few months I have seen as many instances as in 40 years of hospital work: two cases at the American Hospital, Paignton, in one of which Dr. Beal did a successful Antyllus operation; a patient of Mr. R. B. Wright at Chester, to whom I shall refer in connexion with the physical signs; and the two patients we have the opportunity to study to-day—for one we are indebted to the kindness of Captain Mowat, of Sheffield, the other is under the care of Major Ernest Mallam at the base hospital.

Exhibition of Two Cases.

W. W., aged 28, a private, had served in the Northumberland Fusiliers for eight and a half years, was always well and strong and never had a serious illness. On Oct. 19th at about 11 A.M. at La Bassée he received three shrapnel wounds, one in the left thigh. Was in the trenches until 7 P.M. Lost an enormous amount of blood. The fragment entered the left thigh just 3 inches below Poupart's ligament, and the piece is still in the leg. There was a great deal of swelling and a good deal of disability at first. The leg did not change in colour, but he was very weak from loss of blood. The wound did not suppurate. Captain Mowat noticed the swelling in the left leg and felt the murmur. He was at Sheffield from Oct. 23rd to Dec. 10th, and gradually got well. Captain Mowat took a remarkable phonograph record of the murmur, which I heard a few weeks ago at Sheffield.

Now the man is healthy-looking, of good colour; he limps on the left leg; there is no swelling or discolouration. The left thigh looks a little smaller than the right, particularly in the antero-lateral region. There is a healed wound just 3 inches below Poupart's ligament in the lower end of Scarpa's space, where there is a diffuse swelling not very marked, and then a little groove-like wasting in the line of the femoral artery. The greatest prominence is at the site of the entrance of the bullet. The pulsation is diffuse, but does not extend above Poupart's ligament. The veins are not greatly distended, but the internal saphenous is visible, and those on the left side are larger than on the right.

On palpation the characteristic thrill is felt of maximum intensity over the injury, and it is felt down the course of the femoral. There is a slight firm induration just beneath the scar, but not a definite tumour. Pressure on the femoral stops the pulsation at once. The thrill is felt above Poupart's ligament. There is no pistol-shot sound to be felt. Pulsation in the popliteal and tibials not palpable. On auscultation a machinery murmur of extraordinary intensity is heard of maximum intensity at the site of the injury, propagated down the femoral, heard in the popliteal. The arteries are not sclerotic and the heart sounds are clear.

Major Mallam's case is an exact counterpart.

Bullet wound of the thigh on Dec. 30th, passing through Scarpa's space. Much blood was lost, but the orifices of entrance and exit healed rapidly. A large effusion of blood in the upper region of the thigh at first masked the nature of the lesion, and it was not until the swelling subsided that the characteristic signs of arterio-venous aneurysm were noted. There are now moderate swelling in Scarpa's space, pulsation palpable, thrill felt with greatest intensity at the point of maximum impulse, and a loud machinery murmur.

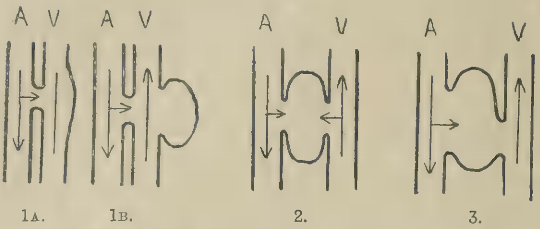
ANATOMICAL VARIETIES AND RESULTING CHANGES.

We need not take time to discuss the anatomical varieties which are all modifications of two types, the simple tangential opening between an artery and a vein—aneurysmal varix, and the formation of a sac communicating with both vessels—varicose aneurysm. The accompanying diagrams (Figs. 1 and 2) from Lexer's "Handbuch der allgemeinen Chirurgie" show all possible forms.

---

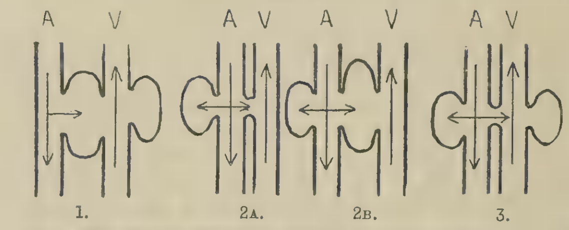
[10] Opera, Ludg., 1676, p. 51.

FIG. 1.



1. Arterio-venous fistula without (1A) and the same with (1B), a venous sac—varix aneurysmaticus. 2. Arterio-venous aneurysm with false intermediary sac—aneurysma varicosum. 3. Arterio-venous aneurysm with arterial sac. Secondary arterio-venous aneurysm.

FIG. 2.



1. Arterio-venous aneurysm with false intermediary sac and varix on outer side of vein, due to double injury of the latter. 2. Arterio-venous aneurysm with immediate communication (A), or with false intermediary sac (B), and with a false arterial aneurysm, due to a single venous and double arterial injury. 3. Arterio-venous fistula with opposing sacs, due to a double injury of both vessels.

The changes that follow are: (1) The blood current is reversed, to a certain extent, in the veins; (2) the blood pressure is increased in them; (3) their walls become arterialised; and (4) the blood pressure in the artery is heightened on the proximal and lowered on the distal side of the lesion. In smaller vessels very slight changes occur. I show you a drawing of an aneurysmal varix of the anterior tibial vessels from a case in the Strassburg clinic, in which a year after the accident the vein was little if at all dilated. In lesions of the vessels of the neck and arms the venous stasis is much less than in the legs, in which the effect of gravitation is so felt that year by year the changes become more pronounced, until, as in the photographs I show, large varicosities and sacculi are formed. Femoral and popliteal arterio-venous aneurysms may last for years without great involvement of the veins, but in a majority of the cases venous stasis forms the most serious sequel of the disorder.

The changes in the arteries on the proximal side of the lesion are less striking, but sooner or later sclerosis occurs with dilatation, and sometimes with saccular aneurysm opposite the orifice of communication. Even within two months of the injury the femoral artery may be felt to be larger and with stronger pulsation (Paignton case). Remote effects on the general circulation are rare, particularly in aneurysms of the vessels of the head and arms. One of my patients (Case 3) died from heart disease which may have had some connexion with his long-standing lesion. In the leg progressive dilatation of the vessels may lead to serious effects. In the case of Captain Mosher,[11] wounded in the middle of Scarpa's space 1898, at the time of death (1911) the dilated arteries extended from the bifurcation of the common iliac to the lower third of the thigh. Hypertrophy of the heart followed, and death from progressive failure of the circulation.

PHYSICAL SIGNS.

In no form of aneurysm are the physical signs so distinctive. *Inspection* may not show much, as in the cases you have just seen: diffuse pulsation at the site of the communication, moderate swelling, but not necessarily any early venous engorgement. In the carotids, subclavians, and axillaries the condition may persist for years without much swelling or great enlargement of the veins. On the other hand, in the form that was so common at the bend of the elbow in venesection days the circulation is much interfered with. Even in smaller vessels such as the occipital the venous swelling may be enormous, as in a patient operated upon by Dr. Cushing at the Johns Hopkins Hospital in 1905. This case illustrates, too, the progressive nature of the lesion, as year by year the vessels on the side of the head grew larger, and after seven years they formed a large pulsating mass which had to be resected, after ligation of the external carotid artery.[12] In the leg, particularly in the situation in the cases you have here seen, venous engorgement sooner or later dominates the scene, and after some years the appearance may be very remarkable, as in the following case.

CASE 1. *Illustrating the development of enormous venous sacculi.*—The patient, aged 31, was shown at the Johns Hopkins Hospital Medical Society on Jan. 16th, 1905. In his eleventh year he had a knife wound just above the right knee; not long after pulsation was noticed along the femoral artery, with marked swelling. He has had good health, with very little disability, except from the increasing varicose veins, which sometimes burst and caused troublesome bleeding. The leg presented a very remarkable appearance, as shown in Figs. 3 and 4. The superficial veins were everywhere varicose; those of the antero-lateral aspect of the thigh were of enormous size, extending into the flank, and many of them were filled with thrombi. The course of the femoral, particularly in Scarpa's space, was occupied by a prominent pulsating tumour, the outline of which can be just seen in Fig. 4. Over this there were an intense thrill and a loud humming murmur with systolic accentuation; pulsation was everywhere forcible. Above Poupart's ligament, lifting the entire iliac fossa and extending into the hypogastrium, was a second tumour, in which the pulsation was very strong, a marked thrill, and the same loud murmur. The size of the tumour, which extended fully 8 inches transversely, can be well seen in Fig. 4. It increased in the sitting posture. The patient said this had been present for many years, but had, he thought, increased in size. It felt very solid and firm and the pulsation was extensile and strong. His only serious disability was from the varicose veins.

The tumours both above and below Poupart's ligament were huge venous sacs. When I demonstrated this case a doubt was expressed whether these really could be venous sacs, but there are many specimens, as in the one I refer to of Dr. Beaumont, and cases are recorded showing a similar condition. A recent one was reported by Eisenberg[13] of a man, aged 65, wounded 18 years before in the thigh, and in addition to great dilatation of the femoral vessels there was a sac 3 inches in diameter of the iliac vein above Poupart's ligament. Additional features that may be noticed on inspection are the increased size of the limb; an actual increase in growth has been noted by Broca in the young; the skin may be much rougher, covered with a thicker growth of hair, and in long-standing cases varicose ulcers are common.

---

[11] Reported in Lagarde's Gunshot Injuries, 1914, p. 281.

[12] Journal of the American Medical Association, Dec. 23rd, 1905.

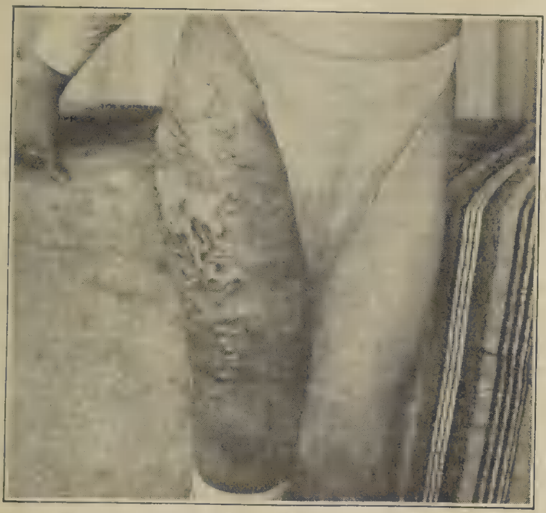
[13] Ibid., Dec. 13th, 1913.

On *palpation* the characteristic thrill is felt, vibratory, rough, continuous, and increasing in intensity with the diastole of the artery. Except in its roughness it is quite unlike any other thrill felt in cardio-vascular lesions, and is pathognomonic. It has an interest, too, as one of the oldest of recognised physical signs, having been described by Antyllus. While of greatest intensity at the site of the lesion, it may be widely diffuse and even felt at the finger tips in an axillary or brachial aneurysm, and at the toes in a femoral. In the patient seen with Mr. Wright[14] at Chester a few weeks ago, there was an additional physical sign which I have never before noted, nor in looking pretty carefully through the literature do I see it mentioned—a pistol-shot sound of great intensity, exactly such as one feels and hears in aortic insufficiency. It was an arterio-venous aneurysm of the popliteal vessels caused by a bullet wound on Jan. 29th. The note which I dictated was:—

> On palpation an intense vibratory thrill, continuous, with diastolic intensification, is felt over the area of pulsation, not below the middle of the leg. The striking feature is the pistol-shot shock felt during the diastole of the vessel, exactly resembling that which one hears and feels in the femoral in aortic insufficiency. It is felt only over the area of pulsation, not in the femorals, and there is no valvular disease. In addition, one feels the strong, firm, aneurysmal pulsation.

In the second case at the American Hospital, Paignton, there was no pistol-shot sound over the popliteal tumour, but one of great intensity could be heard, without the slightest pressure, over the femoral artery. On the other side it could be brought out only with pressure of the stethoscope.

FIG. 3.

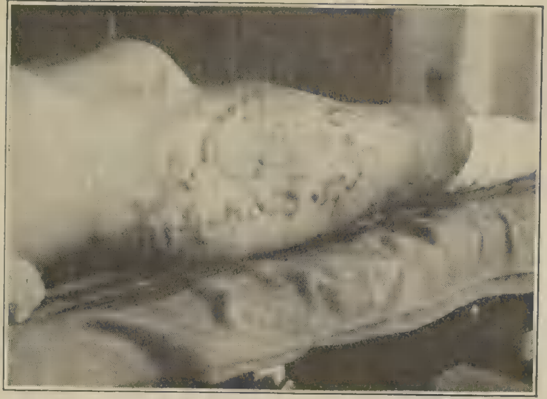


CASE 1.—Arterio-venous aneurysm of the femoral vessels of 20 years' standing.

In the early stages the tumour may not be large, or where it is simply an aneurysmal varix little or no swelling may be present. If there has been effusion of blood the tumour, as in Major Mallam's case, may diminish considerably in size. Subsequently the diffuse swelling may be largely venous, but a circumscribed tumour may be either sacculi in connexion with the vein or artery, or sacculi at some distance from the original site of the injury, and there is not infrequently aneurysmal dilatation of the artery above the lesion.

On *auscultation* the second characteristic physical sign is heard—a loud, rough, humming-top murmur, continuous, with marked intensification during the cardiac systole. During distension of the vessel the murmur is rough, harsh, and vibratory; during its contraction it has a graver, deeper quality. It may be widely diffused, heard up and down the vessels even to the finger-tips in the brachial and axillary aneurysms, and to the toes in the femoral. It may even be intense enough to be heard at some distance from the site of the aneurysm.

FIG. 4.



Same patient as Fig. 3, showing the varicose veins and two huge venous sacculi, one above, the other below, Poupart's ligament.

Practically these are the three great physical signs of arterio-venous aneurysm: the dilatation of the veins, the thrill, and the murmur. Other minor features may be mentioned—absence or lessened pulsation below the site of the tumour, the remarkable influence of posture on the venous engorgement, the pulsation in the peripheral distended veins, the frequency with which phleboliths and thrombi may be felt.

COLLATERAL CIRCULATION.

From the surgical standpoint it is important to determine the adequacy of the blood-supply beyond the lesion. Recumbent the legs, for example, may look alike, but within a few minutes after assuming the erect posture the one on the side of the lesion may become dusky in colour, and the veins dilate. It is not easy to determine the blood pressure in the arteries below the lesion. Korolkow uses a modified Gärtner's tonometer, and Matas lays down the rule:—

> If the peripheral blood pressure is shown by the manometer (a modified Gärtner's tonometer) to be normal or well sustained after compression of the main trunk above the aneurysm then the obliterative operation may be safely applied. If, on the other hand, the blood pressure falls to zero it is evident that the collateral circulation is inadequate, and that no chance should be taken with the obliterative operation or with any procedure whatever (ligature, extirpation, &c.) which would permanently occlude the parent artery.[15]

Another test is after application of an Esmarch bandage apply pressure on the artery above the aneurysm, and note the state of the circulation and the time taken for the skin vessels to fill. In one of the Paignton cases (popliteal) in the sound leg it took three minutes to obliterate the anæmia caused by the bandage while the femoral was compressed above Hunter's canal, but in the affected leg the skin vessels of leg and foot were filled within a minute! The femoral artery on this side felt larger and had a much more powerful pulsation.

---

[14] On March 26th Mr. Wright operated, tying the artery above and below and closing the direct orifice into the vein. There was no sac. The vein was unusually large.

[15] Keen's Surgery, vol. v., p. 273.

RESULTS.

Left alone, what becomes of these cases? Much depends upon the position of the aneurysm. Those in the upper extremities are more favourably situated than in the lower. The following may happen:—

Non-Intervention followed by Good Results.

1. The aneurysm may remain unchanged for years and interfere little, if at all, with the patient's health and vigour. Particularly is this the case with the cervical and axillary vessels. Case 3 of my series illustrates this in a remarkable way, as for years he rowed in races and lived a very athletic life. Case 2 also illustrates the wisdom of non-intervention.

CASE 2.—On April 9th, 1900, Dr. Alderson sent me from Russelville, Kentucky, a man, aged 29. On the night of Jan. 5th he had received four bullets, one in the left shoulder, one in the back of the left arm, one in the left lower axillary region, and the fourth, the important one, entered the middle of the fold of the left trapezius muscle, passed inwards and downwards in front of the spine, and came out under the right clavicle. All the wounds healed rapidly, but at first he had some difficulty in swallowing. The right supraclavicular fossa was occupied by a pulsating swelling extending for about 7 cm. upwards and outwards. There were a marked thrill and a loud humming-top murmur with systolic intensification, which was heard up the neck and down the vessels of the arm. The bullet could be felt just below the clavicle. The tumour had increased, and the question was whether it was safe to leave him alone. This was the policy I urged strongly. Twice he narrowly escaped operation. Two years afterwards I heard from him and he remained well; the tumour was somewhat smaller, but the bruit was still a little troublesome. Five years after the accident I heard again. He had remained well, the tumour had not increased in size, and he was able to use his arm and do everything.

Spontaneous Healing.

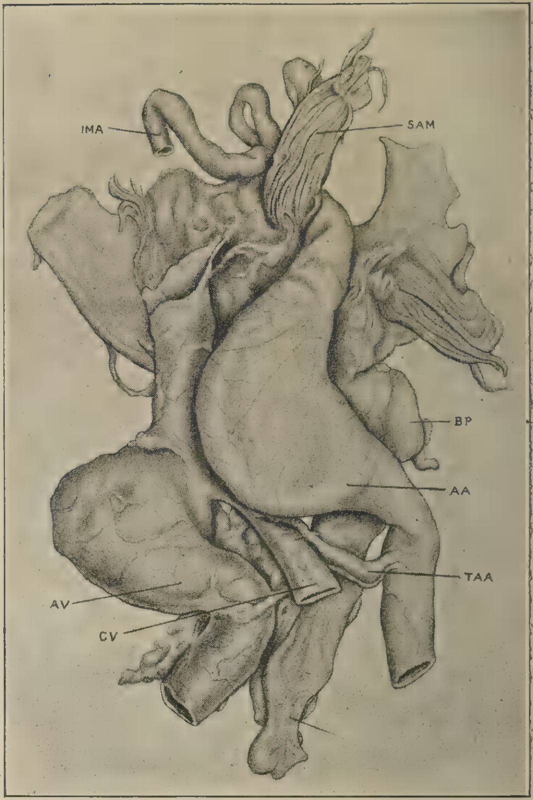
2. Spontaneous healing may occur, the orifice closing between the artery and the vein. This must have happened in Case 3, as a careful dissection by Professor J. J. Mackenzie, of Toronto, failed to demonstrate any communication between the greatly dilated vessels. As such a mode is rare, I give an abstract and a sketch of the dissection. (Fig. 5.)

CASE 3.—I reported the case originally in the *Annals of Surgery*, 1893. In 1878 the man, in running down a sloping grass plot, fell and forced a lead pencil into the arm-pit; a gush of blood followed and the arm became black and blue to the wrist. The aneurysm involved the axillary vessels. He subsequently lived a very athletic life, rowed in the Argonaut Boat Club, and served in the South African War, where he came under Sir G. H. Makins's care. He was invalided in consequence of a sudden pain on the left of the head and neck, and the patient was positive that the tumour had enlarged. He wrote to me on Oct. 17th, 1904, saying that he had marched 610 miles in 32 days and fought 16 battles, with the result of increasing his aneurysm very materially, particularly at the base of the neck. He died in May, 1909, 31 years after the accident, of gradual heart failure.

There are many cases in which the condition has lasted quite as long as this with equally good health; but the special point of moment in this case is that in the careful dissection of the vessels made by Professor Mackenzie no communication could be found between the greatly dilated axillary vessels. The final report in this case was given in THE LANCET of Nov. 1st, 1913. Closure of the orifice is exceedingly rare. Another case is reported by Pluyette[16]:—

A man, aged 33, applied in October, 1904, with a traumatic arterio-venous aneurysm of the right subclavian produced by a revolver bullet. The physical signs were of the usual character. On Nov. 15th he returned to the hospital, having had severe pains in the right hand and arm during the night. The parts were cyanosed, the pulse was scarcely palpable, but what was most remarkable was the disappearance of the thrill and murmur over the site of the aneurysm. There was pain in the course of the arteries, particularly the axillary and the brachial. The radial appeared to be large and hard, and there was no pulsation. It seems to have been an instance of cure by the formation of a thrombus in the arteries.

FIG. 5.



CASE 3.—Arterio-venous aneurysm of the axillary vessels thirty-one years after the injury. S.A.M., Scalenus anticus muscle. B.P., Brachial plexus. A.A., Axillary artery. T.A.A., Thoracico-acromial artery. C.V., Cephalic vein. A.V., Axillary vein. I.M.A., Internal mammary artery.

Occurrence of Sudden Death.

3. Sudden death may occur, either from heart failure or from embolism. Nothing was found to account for the sudden death in Case 4 of my series.

CASE 4.—A man, aged 29, admitted in November, 1904, had received 15 years previously a pistol shot in the lower third of the thigh; following this a tumour appeared, which had been present ever since. There was much disability owing to enlargement of the leg, with great distension of the veins, much lividity, and a persistent ulcer above the ankle. He died suddenly, apparently of syncope. Clinically there was a large pulsating tumour at the lower end of Scarpa's triangle, not easily compressible, with a continuous machinery murmur and a thrill transmitted up and down the leg. Anatomically the condition found by Dr. Rufus Cole and Dr. W. G. MacCallum was very remarkable. The femoral artery was dilated, and at the beginning of the lower third of the thigh presented two perforations separated by a narrow bridge of tissue; the femoral vein just opposite showed a perforation at the same level. A probe could be passed from the artery into the vein through these apertures. On the inner side and in front of the artery and vein, and communicating with both, was a sac 12 cm. in diameter formed of dense fibrous tissue and lined by a granular, deeply pigmented clot. "This sac does not form the communication between the vessels, although the probe passes readily through either into it, nor are they (i.e., the sac and the vessels) directly united, but rather by way of a small space or vestibule which lies in front of the orifice of the sac." The veins were enormously distended both above and below the level of the communication.

---

[16] Bulletin et Mémoires de la Société de Chirurgie de Paris, 1905.

Evidently this large venous sac, which communicated freely with the artery, formed the pulsating tumour to be felt in the front of the thigh.

4. *Rupture* may occur with fatal hæmorrhage, of which a number of cases are recorded.

Disability from Varicose Veins and Thrombosis.

5. In the crural vessels progressive disability may result from the varicose veins, thrombosis, and ulceration. When left too late the condition of the vessels is unfavourable to operation and specially favourable to thrombosis—the surgeon's chief danger. These accidents are well illustrated in the following case.

CASE 5.—A man, aged 34, whom I saw with Dr. Halsted and Dr. Bloodgood, was admitted in May, 1897. Eight years before he was shot in the popliteal space. He did not notice the tumour for a year. It was a large spindle-shaped mass filling the popliteal space, with a well-marked continuous thrill felt over the tumour and far down the leg. The femoral artery was ligatured in Hunter's canal. The leg became gangrenous and had to be amputated. On dissection, just where the femoral becomes the popliteal there was a communication between the vein and the artery, an opening 1 cm. in diameter. Opposite to this on the wall of the artery was a sac measuring 2 by 3 cm. Above the opening the veins were greatly distended and dilated, with thickened walls. At the time of the operation it was noted that some of them were thrombosed and there was a small clot in the artery, and the communication between the artery and the vein was also closed by a small thrombus.

Widespread thrombosis probably accounts for the sudden onset of swelling and disability of a limb many years after the accident. Evidently this happened in the remarkable case reported by Rokitansky.[17]

A man, aged 62, admitted Nov. 28th, 1842, was in 1809 shot in the shoulder. The bullet was removed, but some grains of shot remained. He recovered, but had always a cramp-like feeling in the tips of the fingers of the left hand. For two years there was an increase in the size of the whole arm, which had increased rapidly in the six weeks, and on admission was œdematous and cold, with the skin of a dark red colour. In the arm-pit was an old pulsating tumour the size of a hen's egg, with marked thrill. The subclavian was tied on Sept. 23rd. He died 15 days afterwards of secondary hæmorrhage. There was an arterio-venous aneurysm of the axillary vessels, which were greatly enlarged and sclerotic, and there was a clot in the veins.

And lastly, the vascular tissue involved in the aneurysmal area may take on a nævoid growth. Apart altogether from arterio-venous aneurysm, the entire vessels of a limb, arteries and veins, may take on active growth, as in the extraordinary specimen of macroangiosis of the arm in the Charing Cross Hospital Museum, in which the growth of the vessels followed an injury. This has happened in certain cases of arterio-venous aneurysm of the vessels of the head, and though the orifice of communication may be small, within a few years the vessels (as in Cushing's case already referred to) may become enormously enlarged, much more than can be accounted for by any increase in pressure.

TREATMENT.

It is not my place to speak of treatment, but we all agree, I think, with the conclusion arrived at by Subbotich, senior surgeon of the Belgrade State Hospital, from his experience in the Balkan War, "that arterio-venous aneurysms should be operated upon, as they offer small prospect of spontaneous cure, although they often remain stationary for a long time and cause relatively little trouble." It is a good deal a question of situation and technique. As the cases here reported indicate, with the lesion of the axillary and subclavian vessels good health may be maintained for years without any serious trouble, but there are always risks, particularly of thrombus formation in the distended veins, and even after lasting 30 or 40 years serious trouble may arise. Urgency is greater in the case of the lower limbs, and I should say that it would be very much safer in the two cases we have just seen to operate before the venous engorgement becomes excessive.

A new and truly marvellous technique has been developed in vascular surgery, very largely owing to the work of Alexis Carrel, and the increasingly favourable results in this all-important department of surgery have followed directly upon animal experimentation. It is not too strong a statement to make that up-to-date vascular surgery cannot be done in a hospital whose younger surgeons have not full opportunities to experiment upon animals. The extraordinarily delicate technique of vascular suturing is an art acquired only with much practice. It is a chapter in the history of surgery of which our colleagues may be proud. I was greatly impressed with the statistics given by Matas at the last International Congress of Medicine dealing with operations on aneurysm generally.

Of the 225 cases collected 194 affected the lower limb, 23 the upper limb, 4 involved the carotid artery, 4 the abdominal aorta. Of the whole number, 53·3 per cent. were aneurysms of the popliteal. As to the operation involved, in 150 cases the obliterative operation was done, in 50 the restorative, and in 25 the reconstructive. Of the 225 cases 206 were successful, in 4 cases gangrene followed, and all four operations on aneurysms of the abdominal aorta were followed by death.[18]

Within the next year there will be greater opportunities for vascular surgery than have ever before been offered. The results of the last wars should be carefully studied by our surgeons, those given by Stevenson for the South African, by Saigo for the Japanese, and by Subbotich for the Balkan. The statistics will be found in great detail in the monograph by Monod and Van Vert.[19] They are also given by Sir G. H. Makins in the Bradshaw lecture on Gunshot Injuries of the Arteries,[20] 1913; in Bernheim's (of the Johns Hopkins Hospital) recently issued monograph on "Surgery of the Vascular System";[21] and may I refer the younger army surgeons to the section on aneurysm in "Keen's Surgery" by that modern Antyllus, my old and valued friend Rudolph Matas, of New Orleans.

In conclusion, may I put in a plea for the museums? Specimens should be sent to the Army Medical Museum, Millbank, and to the great Hunterian Collection at Lincoln's Inn Fields; and may I ask that very careful reports of the cases be sent to the Central Committee for preparation of the medical and surgical history of the war, 34, Guilford-street, Russell-square, London, W.C.

THE ETIOLOGY OF RICKETS:

A STATISTICAL STUDY OF THE HOME CONDITIONS OF 400 TO 500 RACHITIC CHILDREN.

BY LEONARD FINDLAY, M.D., D.SC. GLASG.,
VISITING PHYSICIAN, ROYAL HOSPITAL FOR SICK CHILDREN, GLASGOW.

ALTHOUGH it is now over 300 years since Glisson first described "The Rickets," the reason why the bones are deficient in calcium still remains obscure; but so carefully had this pioneer observed the symptoms of the disease that little, if anything, of clinical interest has been added to his classical description. Bland-Sutton[1] and his followers, who include the majority of English and American writers, believe that the cause lies in some error of diet, most probably a deficiency of fat. Marfan[2] has been preaching for many years that it is due to auto-intoxication from the intestinal canal, while von Hansemann[3] puts it down to what he classes broadly as domestication. There are others again—e.g., Moussu[4] and Koch[5]—who have considered rachitis to be of the nature of an infection; and finally, Basch,[6] Matti,[7] Klose and Vogt,[8] and Stoeltzner[9] are of the opinion that the disease arises from an absence of one of the internal secretions.

It is admittedly very difficult to draw conclusions from clinical observations, and especially is this so with regard to the matter of diet in the class of child that suffers from rickets, and accordingly much experimental work has been done towards the elucidation of the problem. In order, however, that one may give due weight to the very various conditions under which different workers have sought to engender the disease, it is necessary fully to appreciate the criteria by which a diagnosis of rachitis can be confidently made. For this end a careful histological examination of the bones is essential. In a growing bone the trabeculæ are composed of calcified tissue studded throughout with bone cells and surrounded by a narrow rind of structureless tissue. The extent of this zone of structureless, or so-called osteoid, tissue varies with the rate of growth, being more abundant the more rapid the growth, but in rachitis it becomes excessive and may be even more abundant than the true bone itself. It is the presence of this osteoid tissue, which may in places almost entirely replace the bony trabeculæ, that is alone pathognomonic of the disease.

Careful microscopic examination has demonstrated two facts—viz., that all examples of spontaneous and experimental rickets in animals described by veterinarians and experimentalists are not identical with the disease as met with in man; and that merely naked-eye or chemical examination of the skeleton (as pointed out by Schmorl[10] and Stoeltzner[11]) has been the cause of a great deal of misconception in the subject. Depending on naked-eye examination, as is well known, was the reason for confusing for so many years congenital syphilitic and rachitic osseous changes.

One cannot lay too much stress on the importance of the histological picture of the bone lesions, nor on the help which a true appreciation of these changes has given us in the valuation of the experimental work of the past and must give us in the experimental work of the future. This same factor, however, has unfortunately tended to confine interest to the bone changes, with the result that the question of general metabolism has been overlooked. From chemical examination of the bones and tissues it would appear that in rickets there is a serious error of the calcium metabolism consisting in the inability of the body to utilise this salt, which as a rule is present in the diet in sufficient amount. Though the poverty of the calcium is found chiefly in the bones, it exists to a certain extent in the other tissues as well.

It is by the investigation of the calcium metabolism alone that a diagnosis is possible in the earliest stages of the disease—i.e., before any bone or other gross changes have presented themselves; and it is the only method during life by which one can declare with certainty that the disease is active. During this period of the disease more calcium is excreted in the urine and fæces together than is ingested with the food, and by watching the behaviour of this calcium interchange the influence of certain factors, curative and otherwise, can be studied. Unfortunately, with the facts at present at our disposal, it is impossible to say whether the calcium, being mainly excreted in the fæces, passes for the most part through the intestine without being absorbed, and is thus conveyed to the tissues in insufficient amount, or whether, as in osteomalacia, a disease considered identical with rickets by many authorities—at least so far as its histology is concerned (Schmorl)—the bones and tissues are unable to fix the calcium which is brought to them in abundance by the circulating blood.

Dibbelt[13] inclines to the former view, but the histological examination of the lesions induced by feeding animals on a diet poor in calcium does not substantiate his contention. Soft bones can most certainly be obtained in this way, but there is a complete absence of the characteristic osteoid tissue. The trabeculæ are thinner and more widely separated than normally, but nature has made the most of the material at her disposal, and all the trabeculæ are perfect in their formation.

The latter theory is therefore more likely, and it is not improbable that the power of the bones and tissues to retain the calcium is dependent on a hormone, the product of some ductless gland. This view of the subject has been suggested by Stoeltzner,[9] who reported rapid improvement in his cases by treatment with suprarenal extract. Subsequent workers, however, have not confirmed his results. More recently Basch, Matti, Klose and Vogt have indicted the thymus gland, and a few months ago Garrod[14] made a strong plea for the hypothesis that some affection of this organ is responsible for rickets. A considerable amount of experimental work has been done on this aspect of the subject, but the results are so contradictory that judgment must be reserved for the present. There seems no doubt that the bone changes after thymusectomy described by Matti are of a rachitic nature, but that they are dependent on the removal of this structure is not so certain. After the operation the animal becomes very lethargic, and the osseous changes do not appear for some considerable time after. Hart and Nordmann[12] state that so long as the animals are allowed a sufficiency of exercise no bad effects from thymusectomy are noticed, and Pawlow[15] some years ago drew attention to the tendency to softening of bones in dogs subjected to operations for biliary, pancreatic, and intestinal fistulæ. Moreover, in rickets and thymusectomy the calcium metabolism shows definite differences. In rickets the calcium is chiefly excreted by the fæces, there being a diminished output by the urine, whereas in thymusectomy, just as in starvation and diabetes, the chief route of excretion is the urine. In this connexion it should also be remembered that in osteomalacia there has frequently been reported an increased calcium output by the urine (von Noorden[16]).

The study of the calcium metabolism also makes it very unlikely that a deficiency of fat in the diet is the cause of the trouble. Freund[17] has shown that while cod-liver oil increases the percentage retention of the calcium of the food, milk fat, on the other hand, causes an increased excretion of the salt, which is just the state of matters obtaining in active rickets. And, further, it is interesting to note that Rosenstern[18] records the case of a child that developed rickets while on a diet rich in fat.

That rickets is of the nature of an infection is a most seductive theory and one against which it is most difficult to argue. Its geographical distribution, its seasonal incidence, and the factors of hygiene which favour its appearance recall very forcibly the behaviour of endemic cretinism, and also that of typhus fever, both of which diseases are probably infectious. There is, however, a dearth of experimental proof in favour of such a conception, and in any case, whether the etiological factor is of the nature of a microbe or not, the infectiousness of the disease is certainly not great, since rachitic and non-rachitic children can be housed together without the latter running any risk of contracting the disease.

Some years ago I carried out an experimental research into the etiology of rickets, and came to the conclusion that the disease could be induced in animals by confinement. These results were embodied in a paper published in the *British Medical Journal* in July, 1908. I may perhaps here mention that Schmorl had an opportunity of examining my specimens, and he expressed the opinion that the bone changes were identical with those found in human rickets. From my experiments there was no evidence whatever that deficiency of fat, or any other dietary error, was a factor in the etiology. All the animals to which a fat-poor diet had been given developed marasmus, and after death none presented signs of rachitis, whereas those allowed a liberal diet of milk and porridge, but deprived of exercise, became markedly rachitic. This is, of course, directly opposed to the earlier teaching of Bland-Sutton, whose experimental results have never been questioned in this country, and have more or less dominated the pathology of the disease ever since.

Bland-Sutton's experiments were carried out in the Zoological Gardens, London, where previous to his researches it had been found practically impossible to rear young animals without them developing rickets. He found that the young were usually fed on lean horseflesh and bones, but as their teeth were not sufficiently strong to crush the bones, and thus extract the marrow, he concluded that the diet must necessarily be very poor in fat. To counteract this defect he administered cod-liver oil, and by this change in the diet alone he reports that he was successful in rearing young animals free from rickets. It is interesting to find, however, that rickets is still a common disease in zoological gardens (in those of London and Glasgow to my own knowledge), and that the superintendents of these institutions do not find it possible by the administration of cod-liver oil to hinder its ravages.

So far as I am aware there is only one zoological garden, at least in Europe, where rickets does not prevail, and that is the most excellent one of Carl Hagenbeck, situated on the outskirts of Hamburg. There the conditions are made to simulate the natural home of the animals, which are not kept cooped up in cages but allowed to roam about freely in parks enclosed by high railings. Trees, earth, and rocks from the natural haunts of the animals are utilised to make the place of exile as like the home conditions as possible. It is not likely that this latter factor has anything to do with the prevention of the disease, and to my mind it is due to the avoidance of "domestication," which, in von Hansemann's opinion, is the chief etiological factor. According to this author, who has written one of the most interesting papers on the subject within recent times, it is the herding of animals under unnatural conditions which induces the disease, and the more remote these are from nature the more powerful is their effect. Von Hansemann has come to this conclusion not only from a consideration of the disease as it occurs spontaneously in the human and animal worlds, but also from that experimentally induced. He remarks in his paper that rickets is unknown in Japan, and in consequence he thought that country a suitable place for conducting experiments.* Through the good offices of one of his Japanese students he got a young wild monkey captured and confined in a cage, and when curvature of the limbs appeared had it sent to him in Germany, where he made a careful histological examination of the bones. The bone changes he describes as identical with those met with in human rickets, and he concluded that they had been brought about by the confinement.

Since the publication of my paper I have heard of several instances in the animal world where confinement or deficient exercise was responsible for the development of rickets, or at least a disease clinically closely simulating it. Dr. John Fergus, of Glasgow, at a discussion on this subject before the Glasgow Medico-Chirurgical Society, related how during the summer his son and niece each had a fox terrier pup of the same breed and of about the same age. His son was able to run about with his pet and thus it obtained plenty of exercise, but his niece, who was unable to do this, had her favourite tethered to a garden seat in order that she might always have it by her. Both were fed exactly alike so far as could be ascertained, and the only difference in the treatment of the two animals seemed to be in the amount of exercise allowed. By the end of the summer the boy's dog was a fine healthy animal, whereas that of the little girl had become so deformed from what Dr. Fergus described as rachitic curvature of the bones that it had to be destroyed.

The following is an extract from a letter which I received from a farmer on the West Coast of Ireland.

> I have learned of a case of rickets in a pup about which I am sure you would like to hear. This pup was fed on a perfect food—new milk, but from the very start was kept confined in the bottom of a barrel, where it was quite

---

* Since the publication of Hansemann's paper several reports have appeared on the question of rickets in Japan. In the year 1906, while examining recruits, rickets and osteomalacia were accidentally discovered by Ogata in the Province of Toyama, which is situated on the western shore of the north island. It would seem that the disease is endemic in this region and, according to folk-lore, to have existed for at least 50 to 100 years. The land is low-lying, very moist, and badly irrigated, and the houses are not so well lit or ventilated as in the rest of Japan. To these factors Ogata is inclined to ascribe the disease, and as a prophylactic measure he suggests that these defects should be removed as far as possible.

> impossible it could exercise itself. One swallow does not, of course, make a summer, and one case of the kind does not prove that rickets is caused by want of exercise, but in the light of your investigations, and the great rarity of this disease in the West of Ireland (I having never seen a case of rickets in the West of Ireland in man or beast), has weight.

Through the son of another farmer in Ireland I learned that his father had noticed that during the winter rickets occasionally developed in sheep which were housed in sheds, whereas those left on the hills, though not so well fed, never showed the slightest trace of the disease.

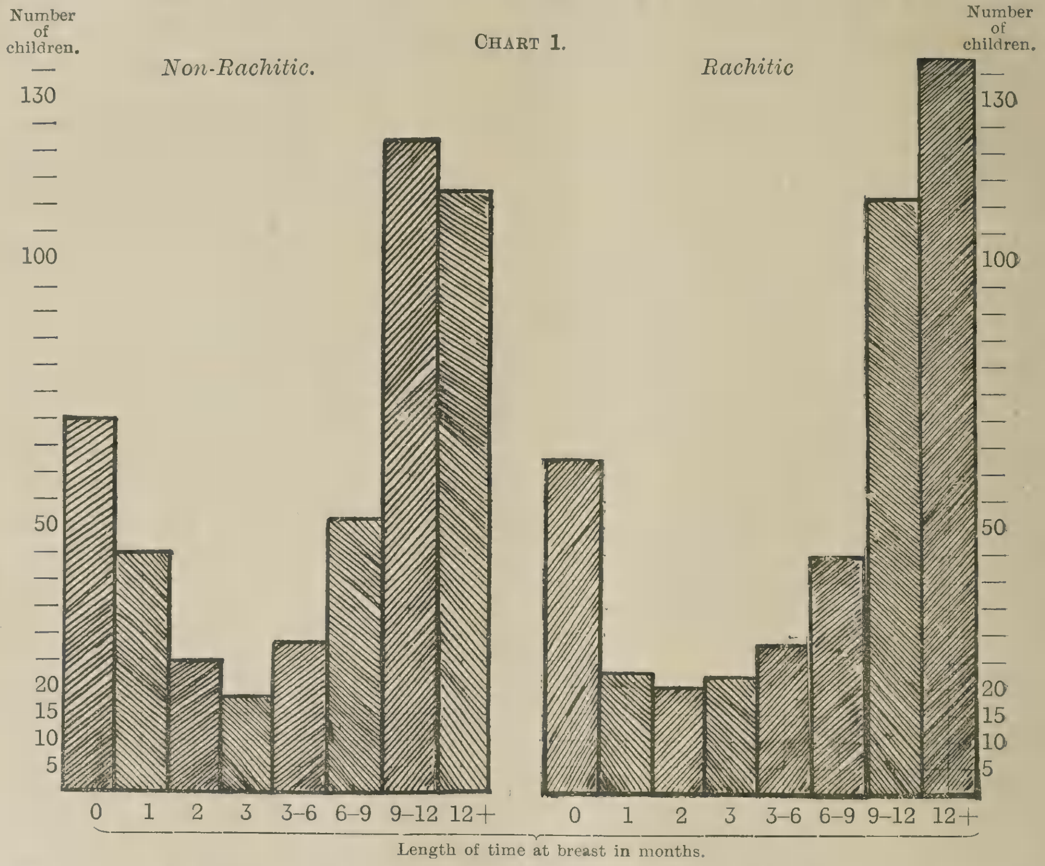

CHART 1.

That exercise has a very definite effect on the retention of calcium is shown by the work of Kochmann and Petzsch.[19] These authors during the course of a research into the factors influencing calcium metabolism encountered one animal in which they found it impossible to bring about an increased excretion of that salt. In the protocol dealing with this experiment it is noted that the animal never was at rest, and the authors concluded that exercise was one factor which strongly influenced the metabolism of calcium. As further exemplifying the effect of exercise in rickets I might perhaps quote from Mayo,[20] who, writing on this malady in 1674, says that "scabies or itching occurring in the course of this disease contributes much to its cure," and to my mind it can only be by forcing the patient to exercise himself that any benefit can accrue.

During the past two or three years I have been collecting information regarding various factors in the life of the rachitic child, some of which have been suggested as predisposing to the disease. The points investigated were: (1) The length of time the child was breast-fed; (2) the order of the child in the family; (3) the condition of the bowels previous to the onset of the trouble; (4) the amount of air space in the house allowed to the child; (5) the number of stairs up the house is situated; and finally (6) whether or not the child has been taken much out of doors. It should perhaps be mentioned that in Glasgow, as in most of the smaller towns in the West of Scotland, the houses are built on the tenement system. These tenements are not usually separated from the street by a garden, and are three or four storeys high. Each flat contains three or even six houses, the number depending on the number of apartments. In the poorer districts of the city houses of several rooms have been subdivided into houses of one apartment, so that many of the common passages are dark and badly ventilated. Other workers, as McGregor,[21] have studied some of these conditions—e.g., the number of stairs up the children reside, but his figures relate for the most part to children in whom the disease was healed, whereas I have taken pains only to utilise facts concerning cases in the active stage of the disease. Whenever possible I have compared the rachitic with non-rachitic children.

Length of time child has been breast-fed.—It has been suggested that denying the child its natural food is an important etiological factor, but my records do not lend support to such an idea. In Chart 1 are graphically represented the number of children breast-fed for varying periods, and in the rachitic as well as the non-rachitic it will be seen that the majority have been suckled for nine months or longer. The similarity of the rachitic and non-rachitic charts is very striking, and disposes not only of the idea that want of breast milk, but also, as has been assumed, that prolonged suckling is at the root of the mischief.

Intestinal troubles (Chart 2).—As mentioned above, Marfan holds that an intestinal auto-intoxication is the source of the trouble, and states that almost invariably there will be obtained a history of some gastro-intestinal disorder for a considerable time before the onset of the disease. My statistics certainly do not support this teaching, since in by far the largest number of the cases the condition of the bowels was described as regular. Although it must be admitted that gastro-enteritis is a not infrequent condition in the class of child which supplies most examples of rickets, marasmus is a more frequent sequel, and marasmic children, as is well known, are not prone to the disease.

CHART 3.

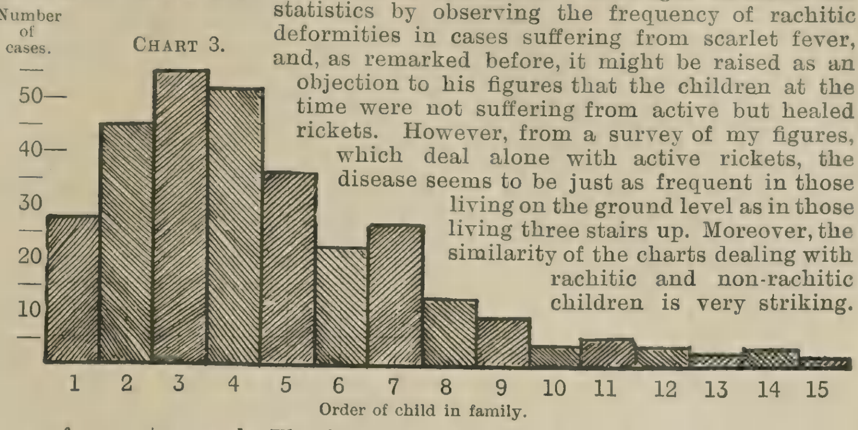

CHART 2.

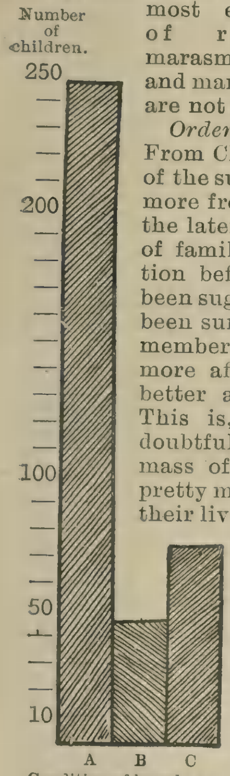


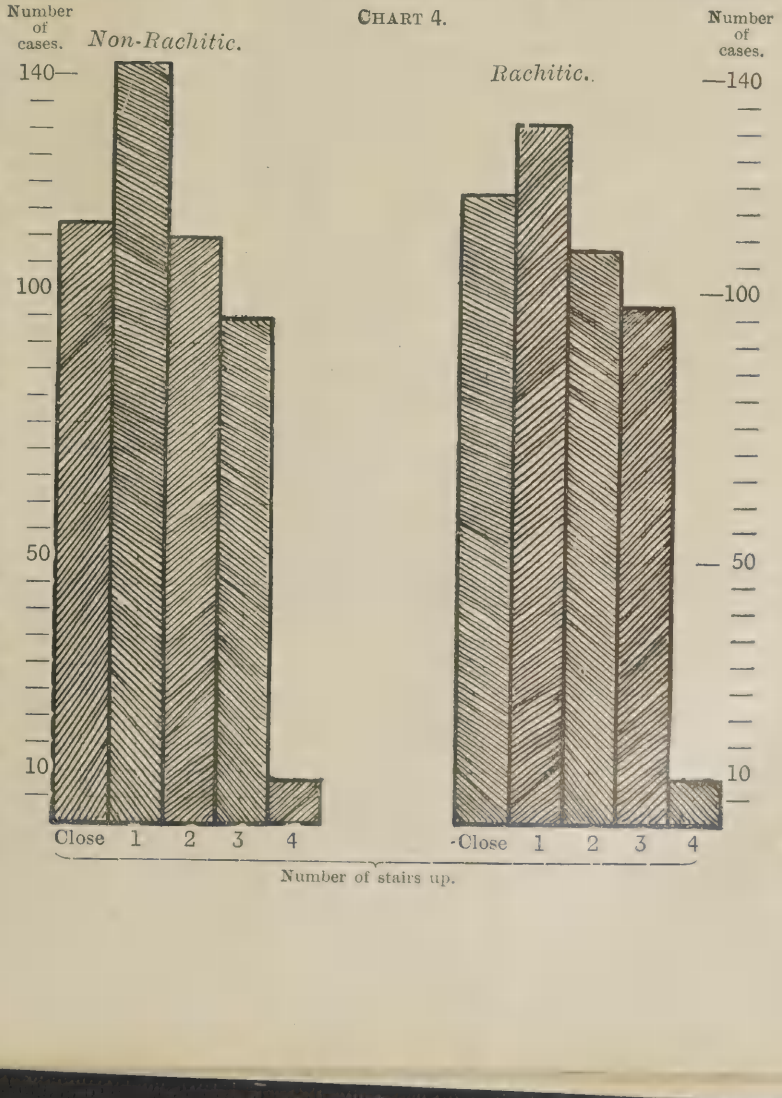
Condition of bowels previous to onset of rickets. A, Regular. B, Constipation. C, Diarrhœa.

Order of the child in the family.—From Chart 3, dealing with this aspect of the subject, it will be seen that rickets more frequently attacks the earlier than the later members of a family. This type of family incidence has attracted attention before, and several reasons have been suggested to account for it. It has been surmised that by the time the later members are born the parents are in more affluent circumstances and thus better able to feed and house them. This is, however, very doubtful, as the great mass of the poor earn pretty much the same all their lives. Again, it has been suggested that the rarity of the disease in the younger members of the family is due to the fact that they are nursed and taken out by their older brothers and sisters, which is, in my opinion, a more likely explanation. It is not improbable, however, that this peculiarity of family distribution is more apparent than real, and is entirely explained by the fact that the majority of families are composed of only four or five children.

Situation of house: number of stairs up (Chart 4).—If want of fresh air plays any part in the etiology of rickets, one would not be surprised to learn that children living in top-flat houses, being probably taken out little, were more prone to the disease than those occupying houses on the ground level. McGregor in his investigations paid particular attention to this point, but he did not find that children living three stairs up were more frequently affected than those in houses on the level of the street. McGregor obtained his statistics by observing the frequency of rachitic deformities in cases suffering from scarlet fever, and, as remarked before, it might be raised as an objection to his figures that the children at the time were not suffering from active but healed rickets. However, from a survey of my figures, which deal alone with active rickets, the disease seems to be just as frequent in those living on the ground level as in those living three stairs up. Moreover, the similarity of the charts dealing with rachitic and non-rachitic children is very striking. The infrequency of the cases resident in houses four stairs up is to be accounted for by the fact that there are very few houses of this type in Glasgow.

Amount of air space in house allowed to each child (Chart 5).—As overcrowding and deficient air space are characteristic of the houses of the class which supplies most examples of this disease, and the very opposite of what prevails in those parts of the globe where rickets is unknown, not only in the human but also in the animal world, it seemed not unlikely that investigation of these conditions in a city like Glasgow would show that they are definitely proportionate to the frequency of the disease. In my researches I have taken one individual per room as the unit, and

CHART 4.

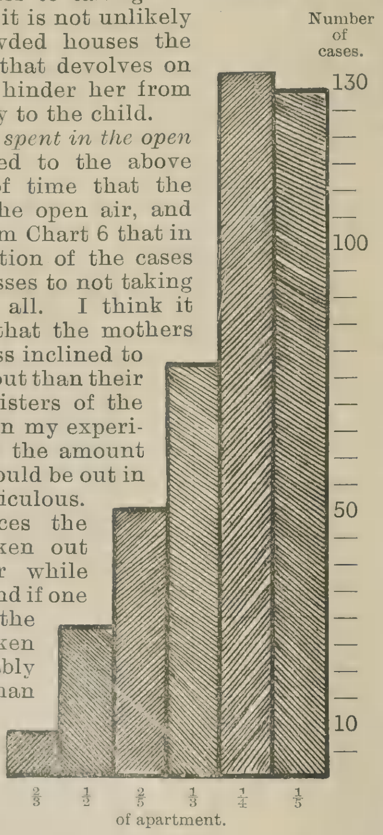


have expressed the amount of air space per child in fractions of this unit. I have not differentiated between rooms of varying size. Examination of my results shows very definitely that the disease is proportionate to the amount of air space allowed to the child, and that as this diminishes in amount the incidence of the disease rapidly increases. Unfortunately I have no figures relative to a series of non-rachitic children of the same class, and it is just possible that the amount of air space is simply a gauge of the poverty of the family, and in consequence other factors than want of air space are in action. The examination of the blood[22] which I carried out some years ago in this disease tends, however, to support the idea that this factor is at work. The average rachitic child showed a higher percentage of hæmoglobin and a greater number of red blood cells than the average healthy child, exactly the condition which is found in persons subjected to a rarefied atmosphere.

Probably the want of sufficient fresh air acts in a twofold manner. In the first place, the absence of pure air will act as a sedative and tend to make the child less inclined for exercise. I have frequently noticed that if a child is confined to the house it is more easily tired, is less active, and wishes to go to bed earlier, so that the living in overcrowded rooms acts just in an opposite manner to taking the child out. Again, it is not unlikely that in overcrowded houses the amount of work that devolves on the mother will hinder her from attending properly to the child.

Amount of time spent in the open air.—Closely allied to the above is the amount of time that the child spends in the open air, and it will be seen from Chart 6 that in the larger proportion of the cases the mother confesses to not taking the child out at all. I think it will be conceded that the mothers of the poor are less inclined to take the children out than their more fortunate sisters of the upper class, and in my experience their idea of the amount of time a child should be out in the open air is ridiculous. In many instances the child is only taken out with the mother while doing messages, and if one gets a history of the child not being taken out it is probably true. It is more than likely, too, that many of my cases included among those allowed out were practically speaking not taken out. These two factors—confinement and deficient fresh air—act, as I have said before, by making the child more lethargic and less inclined to exercise itself, although it is quite possible that deficient oxygenation of the blood itself helps towards the production of the special rachitic metabolic error. The results which I have obtained in the treatment of the disease with massage, passive movement, and electricity are strongly confirmatory of the view that deficient exercise engenders the condition. So far as my experience goes no variety of dietetic or medicinal treatment brings about the same rapid and complete cure. The children are encouraged to walk, and as yet I have not seen any bad effects follow such practice.

CHART 5.



In view of these facts—the effect of deficient exercise on the calcium retention, the influence of confinement in the production of human and experimental rickets, and the frequency with which the disease is encountered in overcrowded houses—I considered it not unlikely that rickets would be exceedingly prevalent in those parts of the world where the people were confined in badly ventilated houses and where sunlight was absent for long periods of the year.

After a fairly extensive search through the diaries and journals of travellers to Iceland, Greenland, and Alaska, parts of the world where the winters are long and dark and where the houses are badly ventilated and devoid of all sanitary conveniences, houses in which many people are huddled together for weeks at a time, I have not come across a single suggestion that rickets is ever encountered. Yet these are just the places where one would have expected *a priori* the disease to have been rampant. True, the Esquimos are described as being bandy-legged, but this is accounted for by the lowness of the roofs of the houses, the heavy ungainly boots that they wear, and the great amount of time that they spend crouched up in their boats. The absence of the disease is the more remarkable when one remembers that for weeks at a time darkness prevails, and during the winter the inhabitants spend most of the time in badly ventilated huts, although it must be admitted that it is just at this season of the year that abundant fat is consumed.
